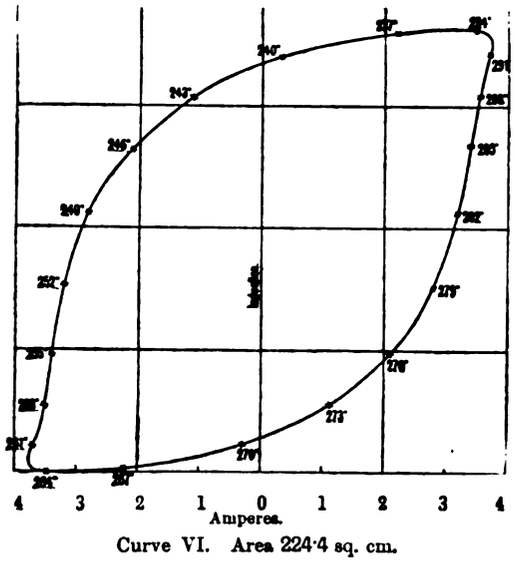
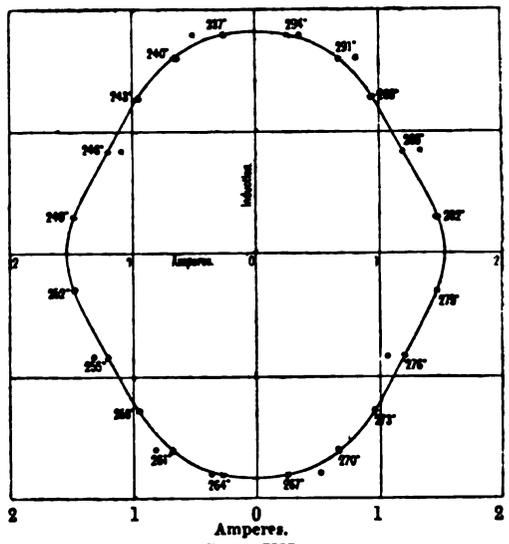
of ordinates from A to B. In this manner a series of points are determined on the curve. Curve VI. shows the relation between induction and magnetising current for the pair of transformers as deduced from the experiments with alternating currents, set forth in Table I. The ordinates in this curve are the area of the curve of potentials of Curve I., for the ordinates of this latter curve are the rates at which the induction is changing, whilst the abscissæ are the currents in the thick wire at corre-



Curve VI. Area 224·4 sq. cm.

sponding times. The points marked ● in Curve VII. give the remainder after deducting the magnetising current as estimates in Curve V., from the currents of Curve VI., that is to say, Curve V. is corrected first for the small difference in maximum induction; then corresponding to any induction the current is taken from the curve, it is doubled as there is only one transformer, and the result is deduced from the corresponding current of Curve VI. The differences are, the magnetising current equivalent and opposite in effect to the local currents in the cores. If the local currents were equivalent to a current in a single secondary circuit, the points ● of Curve VII. ought to have had the form of the full line of Curve VII. drawn through the points +, in which the abscissæ are proportional to the potential difference, and the ordinates to the induction. Returning to Table I., we find that the fall of potential difference on open circuit in the whole combination is 0·8 volt, and that the loss of power in magnetising the cores and in local currents is 222·86 watts, that is a loss for each transformer of 114·13 watts. The total loss of 228 watts may be divided into 126 watts accounted for by hysteresis, and 102 watts due to local currents.

Referring now to Table III. and Curve III. the earlier columns explain themselves, but a word is necessary about the last six columns. The watts supplied to No. 1 are simply the products at each time of the volts at its terminals, and the amperes, passing through, similarly to the watts given out by No. 2. We see firstly that the efficiency of the whole combination with this load is 93·73 per cent., and hence the efficiency of one transformer, if the losses in the two are equal, may be taken as 96·9 per cent. The fall of potential in the whole combination is 6·1 volts; but the fall with no load is 0·8 volt, hence the variation due to the load with constant potential on the thin coil of No. 1 is 5·3 volts, or if the fall of potential in the two transformers were equal, which it is not, for a single transformer, 2·65 volts. Assuming that the transformers are equal, the power lost in resistance would be expected to be the mean of mean current × the difference of potential difference or 215·4 watts. It is, in fact, 150 watts as given by multiplying



Curve VII.

the square of currents by resistances. But the transformers are not exactly equal, and there is the waste magnetic field, both of which will have a small effect on the distribution of loss between the two classes of loss, viz., that by hysteresis, and local currents, and that by resistance, but none upon the gross efficiency.

The other Tables II. and IV. are arranged in exactly the same way as Table III., but the number of observations on Table IV. is insufficient to bring out all the peculiarities of the transformer.

It has already been stated that, if the loss of potential due to load in the two transformers be equal, it will amount to 2·65 per cent. The following experiment was tried to ascertain if this loss was equal:—The transformers were coupled in series as before. The mean potential difference of the thick wire was measured by Thomson's multicellular, and of the thin wire by Thomson's electrostatic voltmeter. The mean of a considerable number of experiments is given in the following table, the load being the same as in Table III., and the results being corrected to the same potential of the thin wire:—

Number.	Full load.		Open circuit.	
	Thomson's multicellular.	Thomson's electrostatic.	Thomson's multicellular.	Thomson's electrostatic.
1	2,380	99·8	2,380	97·0
2	2,380	94·2	2,380	96·2

Digitized by Google

This shows that, of a total drop of 4·8 volts, 2·8 volts occurred in No. 1, and 2 volts in No. 2. There is no doubt of the fact that the drop is greater in No. 1 than in No. 2, which is connected with the waste field between the two coils. Of course these transformers are intended to work exactly as No. 2 is working, in which case the drop from no load to nearly full load, as shown by this experiment, is 2·0 volts. The way in which this waste field causes inequality of drop of potential in the two transformers, coupled as in my experiments, is well worthy of careful consideration. The waste field is proportional to the current in the transformers, or, better, to the mean of the two currents in ampere turns. The electromotive force due to this waste field will be proportional to the rate of change of the current. If the current were expressed by a simple harmonic curve, the electromotive force due to the waste field would also be a simple harmonic curve differing in phase by $\frac{N}{2}$. The curve of potentials is roughly in the same phase as the curve of current. Let A be the amplitude of potential difference of No. 2 transformer, B be the amplitude of difference of potential difference in No. 2, or the potential difference of the thin wire divided by 24. $2b$ will be very nearly the amplitude of difference of potential difference between the thick wires of Nos. 1 and 2. The ratios of potentials in No. 1 and No. 2 will then be $\frac{\sqrt{a^2+-4b^2}}{\sqrt{a^2+b^2}}$ and $\frac{\sqrt{a^2+b^2}}{a}$, or $1+\frac{3b^2}{2a^2}$ and $1+\frac{b^2}{2a^2}$, or the drop in the first from this cause is three times as great as in the second transformer. We shall return to the waste field immediately. Putting aside harmonic curves, and returning to the facts as they are, the following Table V. gives first, half the difference of potential difference taken from Table III. that is at each instant the drop of potential in No. 2, secondly the volts of the thin wire of No. 2 reduced for number of convolutions, this is of course the mean of potential difference between 1 and 2, lastly the squares of these volts. From this we see a mean square 100·8 showing the drop in No. 2 to be 2·6 volts, out of a total drop of 6·1, and the remainder 2·5, the drop in No. 1. Diminishing these results by 0·4, the half of 0·8, the fall observed with no load, the actual losses from no load to nearly full load will be 2·2 and 3·1.

Table V.

Half difference of potential difference.	Volts of high potential coil divided by 24.	Squares of volts.
15·6	−5·0	25·0
14·8	41·3	1706 0
11·3	74·3	5520·0
10·8	102 6	10530·0
11·1	131·3	17240 0
5·5	147·1	21640·0
−1·1	137·0	18770·0
−3·1	119·3	14230 0
−5·9	95·1	9040 0
−12·1	53·4	2850 0

Square root of mean square = 100·8.

Turn now to the last column of Table III. This gives the difference of potential differences corrected for the loss of volts by resistance. It is shown on the dotted Curve III.; this curve presents one or two peculiar features. It should be possible to infer the form of this curve from the curve of current. The rates at which the mean current is changing are as follows :—

268½.. 271½...274½...277½ ..280½...283½... 286½... 289½... 292½... —
30·7 ...24·2 ...19·2 ...18·5 ...13·9 ... 1·7 ... − 9·3... − 12·7... − 21·7... − 28·1

which happens to come to a scale which can be at once plotted. The points marked ● are the points of the curve corresponding with the above rates. The agreement of the points with the curve is remarkably close. This exhibits very completely the effect of waste magnetic field in this transformer.

For half power, as taken from Table II., the rates are as follows :—

268½...271½...274½...277½...280½... 283½... 286½... 289½... 292½ ... 295½
14·6 .. 11·5 ... 9·4 ...10·6 .. 4·4 ... − 4·6... − 7·2... − 7·5... − 13·6... − 17·6

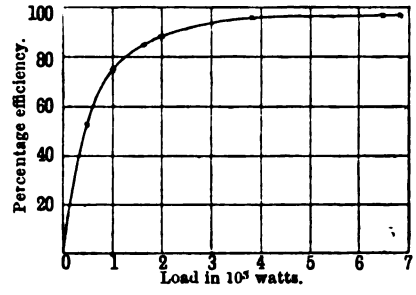
and in the same way in Curve II. the dotted curve represents the difference of electromotive force corrected for resistance, and the points correspond with the above rates.

Curve VIII. gives the efficiencies in terms of the load. This curve is the hyperbole :—

$$\text{Efficiency} = 100.\ \frac{X-(A+BXCX^2)}{X}.$$

Where A = 228, the loss by hysteresis.
B = 0·005, and mainly depends upon the waste field.
C = 0·0000035, and is mainly the loss by resistance.
X = Load in watts.

To sum up, I find that the efficiency of the transformer at full load would be 96·9 per cent.; at half load, 96 per cent.



Curve VIII.

and at quarter load, 84·7 per cent. The magnetising current of the transformer amounts to 114 watts, or 1·75 per cent. The drop of potential from no load to full load is between 2 per cent. and 2·2 per cent.

In conclusion I wish to express my thanks to Mr. Wilson, of King's College; this gentleman carried out the experiments under my direction, and made nearly all the numerical calculations and drew most of the curves for me.

ELECTRIC TRACTION, THE CITY AND SOUTH LONDON ELECTRIC RAILWAY.

BY G. A. GRINDLE.

The use of electrical energy to actuate motors for producing mechanical motion followed closely on the introduction of electro-magnets. The first who seriously applied it to traction purposes appears to have been a Scotchman named Davidson, who, during the years 1837 to 1839, constructed and worked a so-called locomotive capable of carrying two persons. The source of power was a primary battery, and as may be imagined, the motor—or rather motors—were of a very crude description. But the idea was no more than a mere toy, as the car measured 16ft. by 6ft., and the total weight some five tons, while a speed of four miles an hour is said to have been attained. From this time there were many and varied attempts to solve the problem; but the want of a reliable and reasonable source whence to obtain the necessary current militated greatly against any good results; and we may, therefore, pass over the period that elapsed, noting the invention of the Paccinotti machine in 1861, and the subsequent Gramme machine ten years later, till the Vienna Exhibition of 1873, when the first practical and serious demonstration of electricity as a motive power was exhibited,—a Gramme dynamo driven by steam engine, transmitting the current to a similar Gramme machine at a distance of nearly half-a-mile, and from which power was taken to work a pump. Subsequent to this the application of electricity as a producer of motive power progressed but slowly till the summer of 1879, when a small experimental railway was laid down at an Exhibition in Germany. The successful result of this small line clearly foreshadowed what could be done in this direction; and in 1881 an electrical line was permanently laid down for passenger traffic in Berlin, and continues in operation at the present date. In both the latter instances the electric current was gathered from the conductor as the car advanced; but at the close of 1881 the rapid development of storage batteries or accumulators gave fresh impetus to traction work, especially self-contained cars; and many and various experiments and demonstrations have followed, which are of sufficiently recent date to call for no special reference. The bulk, however, of these schemes and experiments has dealt only with light work, such as running of tram cars, and very little until quite recently has been done in what may be termed heavy work, that is to say, running of heavy trains and at considerable speeds. The first step in this direction was the Portrush, Bushmill's, and Giant's Causeway Tramway in the North of Ireland, which was opened in 1883.

* Paper read before the Tramways Institute of Great Britain and Ireland, Tuesday, June 28.

Digitized by Google

This line, when originally opened, was some 6¼ miles in length, and has since been extended an additional two miles. The line runs along the roadside with many very severe curves and gradients, and has a 3ft. gauge. The current is generated by water power, and conveyed to the motor by a rail erected at a slight elevation along one side of the track. The equipment consists of motor cars, but the loads carried are not of very great weight. Steam power traction is also employed in the working of the line, which makes it somewhat difficult to arrive at the actual result and cost of the electrical working.

Following in this came the Bessbrook and Newry tramway, which may be regarded as the first serious attempt to deal with heavy goods, mineral, and passenger traffic. This line was opened for traffic in October, 1885, and, in addition to passenger traffic, has to deal with a heavy goods traffic. The line is a little over three miles in length, running from the Great Northern terminus at Newry to Bessbrook, and is built on private property. The gauge is 3ft., while the gradients average 1 in 80, with a maximum of 1 in 50. The line has practically a steady rise in one direction, against which the motor has to draw a load of 18 tons, plus the weight of car and passengers at the speed of six miles an hour, or a load of 12 tons at nine miles an hour. The power for working the generating dynamos is obtained from turbines at a spot about midway along the line; and the current is conveyed to the motors through a steel conductor laid midway between the main rails. Two motor cars, carried on four 6ft. wheel-based bogies, form the locomotive equipment each car carrying 34 passengers, and weighing 8½ tons, without passengers, and equipped with an Edison-Hopkinson dynamo motor of a normal output of 20 H.P., but which power in practice is often exceeded. The electric generating plant consists of two Edison-Hopkinson dynamos, capable of developing about 25 H.P. each. One only is used at a time, and is found to be amply sufficient for the work required. The designing of the plant and equipment of the line was carried out by Messrs. Mather and Platt, of Manchester, to the plans and under the superintendence of Dr. Edward Hopkinson.

The conditions under which this line was constructed were fairly onerous. An outline of them was published in the "*Proceedings* of the Institution of Civil Engineers," from which I make the following extract:—"The Company agreed to place the line entirely at the disposal of the author for a period of a time, and to purchase the electrical plant at a fixed sum when the above conditions had been complied with, and it had been shown that the cost of working, as evidenced by six months' trial, did not exceed the cost of steam traction on a similar line. The work was commenced in November, 1884, and the line opened for traffic in October, 1885, and was formally taken over by the Company, as having fulfilled the conditions of the contract in the following April. Since that time it has been in regular daily operation. Considerable credit is due to the constructors for the way in which the matter was faced, the risks incurred, and the initiative made in this heavy class of work."

Following on this comes the subject of the present Paper and a short history here may not be out of place. In 1884 an application was made to Parliament for powers to construct an underground line from the City to the Elephant and Castle, and granted. The want of such an undertaking had long been felt and various schemes had been suggested to afford facilities for communication between the City of Londondon and the densely populated districts on the south side of the river, and relieve the congested traffic over London Bridge, which in 1886, when the railway was commenced, was estimated at 7,000,000 vehicles and 56,000,000 foot passengers per annum. The course taken from the line was from a terminal station adjoining the Monument under the Thames a few yards above London Bridge and beneath the Borough, Blackman-street, and Newington-causeway to the Elephant and Castle, following as nearly as possible the line of roadway, and so avoiding the cost of land purchase and compensations. The work of construction was commenced in 1886; and so gratifying were the results of the operations on this first section, involving as it did the difficulties of tunnelling under the Thames, that the Directors applied to Parliament in 1887 for further powers authorising them to extend the line to Stockwell, making in all a distance of some three and a quarter miles. The route for this extension was from the Elephant and Castle along the Kennington and Clapham-roads, with stations at Kennington, Kennington Oval and Stockwell. The work of the extension proceeded concurrently with a completion with the original section, and for obvious reasons the opening of the first portion was delayed until the completion of the scheme in its entirety from the City to Stockwell. Since the opening of the line to Stockwell further powers have been sought and obtained for an extension to Clapham Common. This extension, however, has not yet been carried out, but will doubtless shortly be commenced, and cannot but prove a valuable addition to the undertaking, Stockwell being (at present at any rate) a poor centre for a terminal station. The system of tunnelling is somewhat novel, and introduced into this country by Mr. J. H. Greathead, M.Inst. C.E., to whom the design of the line is due, and under whose able superintendence the construction works were so successfully carried out. Entirely separate tunnels are employed for the up and down lines, so avoiding all possibility of collision between trains approaching each other in opposite directions. The material used in the construction of the tunnels is cast iron, built up in consecutive rings, each ring being composed of several segments with a key piece. The tunnels are driven by a shield which in form may be described as like a tube some 10ft. or 12ft. long with a bulkhead, the internal diameter of the tube being slightly larger than the external diameter of the iron tunnel. A short length of soil is excavated in front of the shield, which is then driven ahead by means of hydraulic power, and the segmental ring is built up within the shield tube in the resultant gap caused by the forward movement between the bulkhead and last built ring of the tunnel. The diameter of each tonnel is about 10ft., the stations are of brick, and usual construction of arch and invert, and have a diameter of 22ft. The two tunnels run as a rule side by side, excepting under the Thames, where one line is directly above the other. The depth of the tunnels below the surface of the roadway varies from 50 to 70ft., and is consequently below all sewers, gas-pipes, water-pipes, and subways, and causing no disturbance to the surface of the roadway. At such a depth the question of ventilation would appear to be a serious one; but. as a matter of fact, the tunnels are self-ventilating, and no special arrangement or machinery whatever is employed to effect what is generally acknowledged to be a very satisfactory state of the air in the tunnel. This is due chiefly to the employment of separate tunnels for up and down traffic, the trains fit the tunnels almost like pistons, with the result that every train is continually changing the air, pushing, so to speak, a column of air to the station ahead, whence it escapes by means of the lift shafts, and sucking air from the shafts of the station last passed. Of course, at such a depth, steam locomotion would be out of the question, and originally it was proposed to work the line by the means of cable haulage; and, in fact, contracts for such means of running were actually entered into. In the interval, however, that elapsed between the first conception of the undertaking, and the time when its accomplishment was in the near future, the application of electricity to traction purposes had been advancing by leaps and bounds; and with the success attained on the Newry and Bessbrook line (on which the loads dealt with as mentioned before were but little if any less than those it was proposed to run on the South London line) Messrs. Mather and Platt were induced to approach the Directors of the line with a view to obtaining their consideration as to the advisability of employing electricity as their motive power in lieu of cable, and to submit a complete scheme for the purpose, together with proposals for the working. The matter was the subject of long and careful deliberation by the Board of the Company, and was warmly taken up by the Chairman, Mr. Charles Grey Mott, to whose untiring energy and deep interest in the matter a great part of the success of the undertaking is due. The submitted scheme was eventually accepted in its entirety, and a contract entered into in the early part of 1889 for the equipment of the line in accordance with the same. In addition to the actual equipment of the line an offer was also made to work the line for a period of 12 months, or, at the option of the Company, to guarantee the cost of haulage according to a sliding scale dependent upon the train mileage run per annum, commencing at 3·5d. per train mile for the full possible mileage of 384,800 miles per half-year. The trains under the guarantee to consist of locomotive 10 tons, three coaches of 4·25 tons each, and 100 passengers. During the summer of 1889 various experiments were carried out on a short length of the line then completed, by a temporary plant at Great Dover-street Station and two experimental locomotives. The experience gained in these trials was at the same time both unique and valuable, affording an amount of information which had never before been attained, and which proved invaluable in working out many subsequent details. In the meantime the construction of the plant proceeded rapidly. In close proximity to the Stockwell terminus of the line, on a large plot of land which serves as a general depôt, a spacious engine-house, in which the entire current employed in working the line is generated, was erected.

The plant supplied consisted of three generating dynamos of the Edison-Hopkinson type, each having an output of 450 amperes at 500 volts. The machines are compound-wound, with bar armatures, and are about the largest machines of the class that have ever been constructed, the total weight of each machine being over 17 tons. The driving is effected by means of link leather belts 28in. wide, and to increase the grip the belt is led under a jockey pulley. Each dynamo is independently driven by a vertical compound engine, designed and constructed for Messrs. Mather and Platt by Messrs. John Fowler and Co., of Leeds. The high and low pressure cylinders are 17 in. and 27 in. internal diameter respectively, and are both steam jacketed. The stroke is 2ft. 3in., normal running speed 100 revolutions per minute, giving a piston speed of 450ft. per minute. The engines are fitted with automatic expan-

Digitized by Google

sion gear on both high and low pressure cylinders, controlled by a high-speed governor driven by ropes directly from pulley on crank shaft. The steam pressure employed is 140lb. per square inch. The fly-wheels are very massive, 14ft. in diameter, 28in wide on face, and weigh 14 tons. Each engine will indicate 375 H.P., and in practice two engines and dynamos are employed, and are amply sufficient to work the entire line, the third engine being kept in reserve. The engines are supplied with steam from six steel boilers of the Lancashire type, 28ft. long, 7ft. diameter, and are fed with fuel by means of Vicars' mechanical stoker. The water supply is effected by means of two Worthington pumps, and before entering boiler is forced through two feed-water heaters, heated by the exhaust steam from engines. Since the opening of the line, and in view of the extension to Clapham Common, a fourth engine and dynamo, similar to the original three, have been erected, also two additional boilers. The boiler-house is below the general ground level, which greatly facilitates the stoking, the fuel being simply tipped straight into the hoppers, and so avoiding all cost for elevating, &c. Adjoining the engine-house is a fitting-shop, where minor repairs can be carried out. From the dynamos the current generated is conveyed by means of lead-covered cables to a massive but simple switchboard, and is there distributed to the feeding mains. These mains or cables, of which there are four, are of the well-known Fowler-Waring manufacture, and consist of a 61/14 B.W.G. copper core, insulated with patent insulating material and lead-sheathed. The cables are carried on brackets along the sides of the tunnel, and led into the various signal-boxes. In the signal-boxes are fixed small slate distributing boards, fitted with plugs and fuses, and from these the current is conveyed to the working conductor by means of feeder cables. The working conductor is of steel, of channel section specially rolled for the purpose, and of such composition as to ensure its having a low specific resistance. It is carried by glass insulators, which are cleated with creosoted blocks to the sleepers, and laid between the two main rails at a distance of about one foot from each rail; this position being rendered necessary on account of the low position of the central buffer coupling. The lengths of conductor are fixed with two small fish-plates and four bolts, as a mechanical coupling, while the electrical connection is ensured by means of a laminated copper strip, secured by four copper rivets. The steel conductor is not continuous, but broken at every station. The intervening gap, a length of some two feet, being made up with a piece of well-seasoned oak, by which means it is possible to isolate any one section of the line without interfering with the remaining sections, or in the case of any accidental failure occurring on any section it automatically disconnects itself from the system. At the points and crossings, which are in every respect similar to ordinary railway practice, the shoes or collectors have to be lifted over the crossing rail, the level of the conductor being one inch below that of the main rails. This is accomplished in a simple and effective method by means of inclined wooden planes, up which the shoes run. The insulation throughout the line is exceptionally high. The daily test of the entire system, which includes generators, switchboards, cables, feeders, working conductor, points and crossings, locomotives, and lighting circuits with the full pressure of 500 volts, does not give a leakage current of one ampere, or considerably less than 1 H.P., and is often as low as one-fourth of an ampere. The conditions of the line naturally are highly favourable in this matter, no difficulty with weather having to be contended with. The return circuit is made by means of the main rails, which are connected in addition to the ordinary fish-plates with copper connecting strips, fixed in the same manner as in the working conductor.

The electric locomotives, of which fourteen were supplied for working the line, were each designed to be capable of exerting a tractive force of 3,000lb., and running at a speed of 25 miles per hour. In general appearance the locomotives closely resemble steam tram motors. The weight of each locomotive is 10 tons, and it is carried on two axles, with a wheel base of 6ft. In the construction of these motors a striking and novel departure from anything that had previously been attempted was made with regard to the armature. Instead of being, as in previous engines, connected with the driving axles by means of gearing belts or chains, the armatures were actually built up on the axles themselves, thus entirely obviating all the necessary incumbent complications that had hitherto been in vogue. The magnets are supported partly by the axles and partly suspended from the car itself, an arrangement which allows of a certain amount of freedom of angular motion round the axle, yet always remaining concentric with the armature. A separate and independent motor is fitted on each axle. The motors are series-wound, and the armature revolution per minute, of course, varies with the speed of the train. At twenty miles per hour the revolutions are approximately 250 per minute. The current is taken from the working conductor by means of three sliding shoes fixed by hinged supports to the frame. The shoes are of cast iron, and it is found in practice that they will run about 10,000 miles before requiring renewal. From the shoes the current is carried by an insulated cable to the main-resistance switch, which controls both motors. The resistances are placed in series with the motors, and gradually cut out as the switch is put over. A second switch controls the reversing movement, which is effected by changing the direction in which the current passes through the armature. The locomotives are fitted with hand and air brakes, the latter being of the well-known Westinghouse type, and continuous throughout the train. To work the air brake a supply of compressed air is carried in two steel reservoirs on the locomotive, and replenished at Stockwell on every round journey. Connection between the locomotive and carriages is effected by means of a central buffer coupling. The trains are made up of three coaches, each constructed to carry 34 passengers, open from end to end, with two longitudinal seats like those in an ordinary tramcar. Entrance into the cars is gained by means of end doors, and between the carriages intermediate platforms are fixed, fitted with collapsible side gates. The carriages, which are 29ft. over all, are carried on two four-wheel trucks, and, exclusive of passengers, weigh over 7 tons each. The lighting is effected by means of incandescent lamps, supplied with current from the working conductor.

The gauge of the line is, standard, 4ft. 8½in., and the rails, 60lb. weight per yard, are of Ebbw Vale steel. The track is not ballasted, the cross sleepers merely resting on the sides of the iron tunnel. The road has many severe curves and gradients, the sharpest curve having a radius of 1½ chains, and the heaviest gradient being 1 in 14 with, and 1 in 25 against, the load. A complete telegraphic and block signalling system is carried throughout the line. Such is a brief description of the line and its equipment, the entire electrical portion of the latter being constructed by Messrs. Mather and Platt, of Manchester, from the designs, and under the superintendence, of Dr. Edward Hopkinson, a partner in the firm.

A few words on the working and results may, perhaps, be of interest. On November 4, 1890, the line was formally inaugurated by his Royal Highness the Prince of Wales, who, accompanied by his late Royal Highness the Duke of Clarence, made the journey from the City to Stockwell, and visited and inspected the plant and works. Shortly after this the line was passed by the Inspectors of the Board of Trade, and eventually opened for public traffic on December 18, 1890.

Upwards of 18 months have therefore elapsed since the public opening, during which time the line has been in daily operation. For the first few months a train service of some twelve trains per hour each way was maintained; but with the growing traffic this has been increased, until at the present time, during the busy hours of the morning and evening, as many as 16 and 17 trains per hour are run. The public appreciation of the line is shown by the increasing numbers of passengers carried. For the half-year ended June 30, 1891, the number of train miles run was 141,408, and passengers carried 2,412,343. For the second half-year ended December 31, 1891, the train mileage run was 188,666 miles, and passengers carried 2,749,055, exclusive of season ticket holders, the revenue from which on the average fare would represent 37,300 additional passengers, or a total of 2,786,355. The revenue receipts and expenditure have been for the first half-year—receipts £19,637, expenditure £15,520, or a balance to the good of £4,117. For the second half-year—receipts £20,243, expenditure £15,516, balance to the good £4,727. These figures are significant when compared with the train mileage and passengers carried, 47,258 train miles more having been run and 374,000 more passengers carried during the second half-year; while the total expenditure has been £4 less, which reflects much credit on both the General Manager and Engineer, Messrs. T. C. Jenkin and Basil Mott, for the manner in which the working of the line has been conducted. It is to be regretted that this meeting was not a few weeks later, when the results of the present half-year would have been available for comparison; but to date since the opening of the line the total mileage run is over half a million miles, and the number of passengers carried upwards of seven millions. The percentage of expenditure to receipts may appear high, but a careful study and analysis of the figures show that this is not abnormally due to the traction expenses—the cost of locomotive and generating power, including salaries, office expenses, general superintendence, running expenses (including wages connected with the working of locomotive and generating engines, coal and coke, gas, water, oil, tallow, and other stores), repairs and renewals including wages and materials—only amounting to 40 per cent. of the total expenditure, or 30 per cent. of the gross receipts, which, I venture to submit, will compare favourably with any other mode of traction. From these figures it will be seen that the cost per train mile for the last half-year was just under 8d., while under the sliding scale before mentioned the cost per train mile on the mileage run would have been 7·125 pence. But in the actual cost of 8d. drivers' wages and other items are included which were excluded in the sliding scale, and, if deducted, bring the actual cost down to 5¼d. per train mile. This, I think, will be generally admitted as highly satisfactory, especially when the serious increase of the train load (no less than 40 per cent. above that originally stipulated for),

Digitized by Google

caused by the increased weight of carriage, is taken into consideration—the total train load for the 5¼d. per mile being 42 tons. The working of the plant and line has been both regular and satisfactory.

On no single occasion during the whole period that the line has been in operation has there been any accident or stoppage of the generating dynamos, showing conclusively the security and certainty with which electrical plant can be worked. Slight delays have occurred from time to time with the locomotives; but these have, in almost every instance, been distinctly due and traceable to the unexpected load and strain put upon them, and in spite of which the record of work done by these locomotives will compare favourably with that accomplished by steam locomotives. The average mileage of the locomotives in regular use during the past year has been no less than 27,000 miles, while on a well-equipped steam road the average is 20,000 to 23,000 miles per locomotive. The success of the line is further shown by the numerous similar projects which have followed. Last year a Bill was passed through Parliament authorising the construction of the Central London Railway, a line seven miles in length, extending from the City to Bayswater to be constructed in the same manner, and to be worked electrically on similar principles, but on a much larger scale. During the present Session no less than six Bills have been presented applying for powers to authorise the construction of similar undertakings. Of these six Bills, four of which are applications for new lines, and two for extensions of existing powers (including the extension of the City and South London line to the Angel, Islington) three have passed through both Houses, namely, the Baker-street and Waterloo line, the Great Northern and City line, and an extension to Liverpool-street of the authorised Central London line. The Great Northern and City line running from Drayton Park to Finsbury-pavement is of exceptional interest, being intended to relieve the Great Northern traffic, and over which it is proposed to run the ordinary rolling stock of the Great Northern railway. The above Bills in the first instance were referred to a Joint Committee of both Houses appointed to consider the whole question as to the best method of dealing with the electric and cable railways schemes, and to report their opinion as to whether underground railways worked by electricity or cable traction are calculated to afford sufficient accommodation for the present and probable future traffic. The Joint Committee, after having met on several occasions, and having had submitted to them a large amount of evidence, reported strongly in favour of the various schemes, and with regard to electric traction as follows:—"The Committee report that the evidence submitted to them was conclusively in favour of the sufficiency and special adaptability of electricity as a motive power to the proposed underground tubular railways."

It may, therefore, be assumed that before very long this system of transport will become fairly general in London, affording, as it does, a cheap, rapid, and safe mode of conveyance. On the table is a small model of the Bessbrook and Newry motor car, also a model locomotive of the same power as the City and South London line, and but little more in weight, with Hopkinson's patent double motor, in which a single magnetic circuit embraces both armatures, the motors being carried entirely from the framework, and, therefore, on springs, and driving the axles by diagonal connecting rods, according to a plan devised by the late Mr. Lange, of Messrs. Beyer, Peacock and Co. (Limited). The photographs round the room are various views of the plant, &c., of the Bessbrook and Newry and the City and South London lines.

LONDON CHAMBER OF COMMERCE AND OVERHEAD WIRES.

On Wednesday afternoon last a deputation, consisting of Sir Vincent Barrington, Major Flood Page, and Mr. Henry Edmunds, representing the London Chamber of Commerce, waited on Sir Courtenay Boyle to urge certain objections to the Overhead Wire Byelaws as drafted by the London County Council.*

The deputation was introduced by Sir V. K. Barrington, who said that, as a member of the Council of the London Chamber of Commerce, he ought to mention that the Electrical Trade Section was one of the strongest sections of that body, and it fairly represented the electrical interests of the metropolis. Great anxiety was felt about this matter of overhead wires, and the size of the deputation gave no indication of the interest and importance attached to the subject, since an important Congress of Chambers of Commerce was being held elsewhere, and prevented many from being present. The object of the deputation was to make certain representations on behalf of the Electrical Trade Section of the London Chamber of Commerce with regard to the byelaws regulating overhead wires which had been drawn up by the London County Council. Government departments now paid more attention to trade interests than was formerly the case, and although the interests of the public must of necessity come before those of any section of the community, still he would submit that it was possible at times to push the former to such an extent that the latter were injured without any appreciable benefit to the public at large. He would ask Major Flood Page to deal with the matter in detail.

Sir Courtenay Boyle pointed out that it was a little irregular after a matter had been discussed to hear *ex parte* statements from one side alone, but as, much to his regret, the London Chamber of Commerce had not been represented at the public inquiry previously held, the Board of Trade had, in consideration of the peculiar position occupied by the London Chamber of Commerce, decided to hear them further on the subject.

Major Flood Page then proceeded to deal with the various clauses in detail, and in reply,

Sir Courtenay Boyle announced that the following concessions had been made. In Clause 1, positions of all wires were to be marked by the company owning them, on a map (of a scale of 25 inches to the mile), to be provided by the London County Council. The period of registration was also extended from three to six months. In Clause 2, "not more than one month after," was to be substituted for "not less than 14 days before." In Clause 4, 6ft. was substituted for 7ft. as the minimum height of wires over roofs. It was also decided that some mark indicating the date of erection should be placed on each pole, but not necessarily the date itself; also where wires belonging to several companies were fastened to one pole, the company owning that pole should be deemed responsible for the condition of all the wires attached to it. With regard to the question of access, Sir Courtenay Boyle said he was afraid he should not be able to give the deputation much satisfaction. The question had received the most careful consideration at the hands of the Board of Trade. The clause had been amended so as to require that reasonable notice should be given to the Company that inspection was to be made, but he could not promise more. He had taken care that the views of the London Chamber of Commerce should be put in the strongest possible manner.

Major Flood Page said that the National Telephone service was admittedly bad, indeed, Mr. Forbes himself had acknowledged it, but it was because they had not the powers which Parliament said they ought to have, and they could not put their wires underground. They sent 160,000,000 messages as compared with 6,000,000 sent by the Post Office, and he thought it was absolutely necessary that they should have as free a hand as their partners, the Government, in this matter. It would be almost impossible, he thought, to obtain wayleaves if they had to give security for inspection and entrance by the officers of the Local Authority.

Sir Courtenay Boyle, while not holding out any hope that any further amendment could be made, promised to lay the matter before the President of the Board of Trade.

The deputation then thanked Sir Courtenay Boyle for his courteous reception and the trouble he had taken in the matter, and withdrew.

PRICING GOODS AT THE COLUMBIAN EXPOSITION.

The following extracts from a leading article in last week's *Engineering* form an appropriate supplement to our own brief comments:—

It was obvious from the commencement that there could be no British Section at all unless one point of vital importance was definitely fixed. This point referred to certain privileges being accorded to foreign exhibitors in regard to affixing prices on the goods they would display. At the Centennial Exhibition of 1876 this matter was unaccountably overlooked, and after it was too late to withdraw, foreign exhibitors found themselves compelled to submit to the damaging necessity of increasing the prices attached to their goods by the amount of duties then enforced. On account of this regulation, a great part of the benefit that would otherwise have accrued to foreign exhibitors was lost, and the unfortunate impression which this policy produced has never been effaced. . . . Bearing these things in mind, it was obvious to the Royal Commission that the widest privileges in the matter of pricing exhibits should be assured to manufacturers, in the clearest and most unmistakable manner, before they could be asked to undertake the trouble and expense of forming a British Section at Chicago.

In September last this all-important subject was laid before Mr. Foster, the Secretary of the Treasury, by the English and German Commissioners, the exact wording of the demand being as follows: Exhibitors of goods sold for delivery after the close of the Exhibition should "in all cases be at liberty to mark them for sale at

Digitized by Google

such prices as they may think fit, entirely irrespective of all customs dues, such dues being paid to the Treasury agents by the purchaser prior to his removing the goods he has bought, after the close of the Exhibition." In the presence of Mr. Butterworth, the solicitor-general to the Exposition, and of Mr. McCormick, the American representative in England, Mr. Foster assured the Royal and Imperial Commissioners that there could be nothing to prevent foreign exhibitors from marking their goods in the manner desired, that is with the bonded prices. A few days later satisfactory assurances on the subject were given to the Commissioners by Colonel Davis, Director-General of the Exposition in Chicago, and so lately as February last they were formally repeated in correspondence passing between the Royal Commission and Colonel Davis. As soon as this vital point had been settled, the Royal Commission was enabled to approach manufacturers and to give them the assurance that they would be privileged to price their goods exclusive and inclusive of duty. Without such an assurance it is certain that the limited success that has been achieved would have been unattainable. Acting upon the guarantees of the Commission a certain number of manufacturers are preparing to go to Chicago next year, and the recent discovery of a policy intended to nullify the undertakings of Colonel Davis, and to deprive British exhibitors of their only important privilege, has produced a profoundly painful impression, not only among manufacturers, but on all those in England who have the interests of the American Exposition at heart.

It is obvious that this circular had never been communicated to the Royal Commission, because their official handbook for exhibitors, of a much later date, still contains the clause guaranteeing manufacturers the privilege of pricing their goods free of duty. Moreover, had the circular containing this strange departure from the original undertaking been so communicated, the Royal Commission would most certainly have lost no time in informing exhibitors. So limited, indeed, has been the publicity given to this document that it is within our own personal knowledge that some of the most influential men in Chicago connected with the Exhibition were, until very recently, unaware of its existence. Of course it would be wholly improper to pass judgment at present upon this act of the Director-General. The Royal Commission, who recently sent their secretary to Chicago, will undoubtedly give him the most stringent instructions to protect British exhibitors and to maintain the original guarantees intact. But the amplest assurances upon this point will not be sufficient to remove the unfavourable impression from the majority of our manufacturers, who are already unreasonably prejudiced against the commercial and political methods of the United States; and even if this matter is cleared up, many of them will ask what unforeseen dangers still await them.

The "privilege" accorded by Colonel Davis to foreign exhibitors, of affixing the actual cost price of goods is simply absurd; while the alternative of adding duty to the selling price, or of paying the duty themselves, is one which may reasonably determine manufacturers already well disposed to abstain altogether. Under the most favourable circumstances this incident must be regarded as a deplorable one; under very possible conditions it may result in limiting the Columbiam Exposition to a national celebration.

Pending definite explanations and renewed assurances, it may not be out of place to point out here that the circular of Colonel Davis is probably the result of political pressure, combined with the well-known objection of many American manufacturers and merchants to meet European competitors at Chicago next year. Politics are inseparable from all great undertakings in America, and the Columbian Exposition could be no exception to the rule. Republican and Democratic factions have each their grip upon the World's Fair, and while for every reason, excepting possibly that of commercial competition, the latter party would prefer above all things to see foreign goods priced free of duty, the former would resist to the utmost any such privileges being accorded; in fact, the concluding paragraph of Colonel Davis's circular shows clearly how much afraid advanced Protectionists are of allowing the masses in America to know what protection costs them, a lesson which they certainly would learn to some purpose from the low-priced goods in the foreign sections of the Exhibition.

In conclusion, we would point out to intending British exhibitors not to arrive at any hasty conclusion on the subject of the Davis circular, but to await the information that will doubtless be accorded them without delay by the Royal Commission, who is responsible for protecting their interests. At the same time it will not be unreasonable if manufacturers express their opinion on the subject of these restrictive regulations, and express it in no uncertain voice, that shall be heard as far as the City of Chicago.

LEGAL INTELLIGENCE.

Lane Fox v. Kensington and Knightsbridge Electric Lighting Company (Limited).

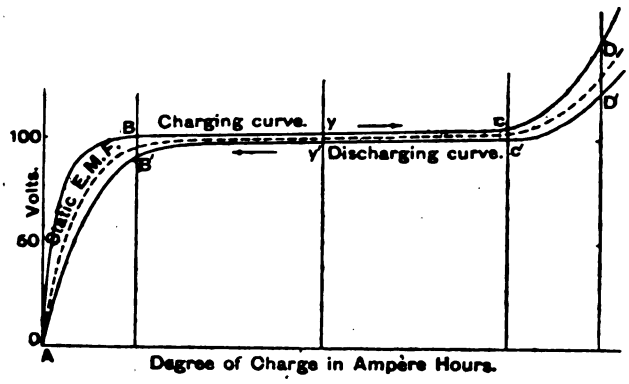
In the Court of Appeal on Monday, June 27th, before Lords Justices Lindley, Lopes, and Kay, Mr. St. G. Lane Fox appealed against the decision of Mr. Justice A. L. Smith in the Chancery Division in his case against the Kensington and Knightsbridge Electric Lighting Company. This case was reported in *The Electrician*, Vol. XXVIII., p. 437 *et seq.* The judgment was given in *The Electrician*, Vol. XXVIII., p. 580.

Mr. LANE FOX commenced by apologising for any inconvenience to which he might put the Court by conducting his case in person. He said that it had been remarked that there had been an unexplained delay in bringing the action. He attributed this to two causes. First, the industry was at the time of the patent entirely new. He had been led to study the distribution of electric lighting by some experiments which he had carried out in the lighting of gas-lamps in Pall-mall. There were several entirely new ideas—that of constant pressure was new, and was, indeed, contrary to what was believed possible by the electrical authorities of the day. Another reason for the delay was that there were no workmen at that time, and men had to be educated. He had thus educated a large number of men. One of the important parts of lampmaking was the glass blowing, and glass blowers used to get £4 to £7 per week. There had been a cross action in the case of "Brush *v.* Holland," in which this patent had been brought forward; and in a compromise the Edison Company admitted the validity of the patent, and the Brush Company gave them a licence; but he had not ratified this licence. In beginning the explanation of the scientific part of the case, the plaintiff explained that according to his invention, the conductors or mains ramified all over the district under a constant pressure. He would use the terms "electromotive force," "difference of potential," "pressure," and "voltage" to mean the same thing. Lord Justice Kay remarked, "We have a certain general knowledge, nothing like your own, of course, of incandescent lighting." Variations of pressure were possible for many reasons, and might take place suddenly; he, therefore, thought that a buffer of some sort was desirable. He suggested in his patent that several batteries for this purpose would be desirable. It was inevitable, of course, that the mains should have some resistance, but he had conceived the new idea of a low-resistance main and of high-resistance lamps. He had described in his patent a lamp which was typical of those in use at the present day, having a luminous surface proportioned to the amount of light, and a high resistance. Mr. Lane Fox then discussed the alleged disconformity between the provisional and the complete specification, and the question whether the general claim for the advantages of his invention was set forth in the provisional specification. He said that Mr. Justice A. L. Smith had drawn a distinction between "regulation of pressure" and keeping the pressure constant. It had been alleged that although the regulating device had been struck out by disclaimer, the regulation was retained, and he argued that keeping the pressure constant was the same thing as regulating. Mr. Justice Kay said that there appeared to be two modes of regulation described in the specification; the one by an electrometer, and another by means of a secondary battery, which would supply any deficiency, whether caused by change of speed of the dynamo, or by change in the number of lamps. Mr. Lane Fox called attention to a passage in the judgment (*The Electrician*, Vol. XXVIII., p. 580, three-quarters down the second column), in which Mr. Justice Smith said that "by coupling up secondary batteries to his system of distribution of electric current, he might be able to neutralise the pressure of the mains." Lord Justice Kay thought that this must be a mistake for "equalise," and after a little discussion it appeared to be admitted that this must have been the case, but the original judgment would be examined. He then referred to another passage in the judgment in which the opening speech of the Attorney-General was quoted by the Judge (*The Electrician*, Vol. XXVIII., p. 582, top of second column), where he used the words "absolutely maintained at a constant pressure." Mr. Lane Fox thought that these words of the Attorney-General were too strong, for he could not and never had claimed absolute constancy of pressure, and he thought that Mr. Justice A. L. Smith, when quoting this, had in his mind that he was claiming too much. Line 34, p. 2 of the specification, said that the electromotive force of the conducting mains should be kept as nearly as possible constant. With regard to the alleged disconformity, Mr. Lane Fox said that supposing there was no claim in the provisional specification for the use of secondary batteries, he could not use them for regulating as described in the complete specification, and cited "Nuttall *v.* Hargreaves." Even if a distinction could be drawn between regulation and keeping the pressure constant, this objection could not apply, since he had only amplified the invention in the complete specification. There was nothing in the title to cover the combination which he claimed as his invention, except the word "regulating." In the specification he had said, p. 2, line 48, that it was "necessary to have some regulator." He regretted that the word "necessary" had been used; for further experience had shown that no such regulator as that which was described in the patent, and afterwards cut out by disclaimer, was really necessary. He said that he did not understand what Mr. Justice A. L. Smith had meant by making a difference between regulating and keeping the pressure constant. The three judges held a consultation together for some time at this point; and Lord Justice Lindley then said that the object of this invention was clearly for keeping the pressure constant, and that there were two things described for doing it. The inventor had found by experiment that one of these was not necessary. He now admitted that it was unnecessary, and the use of the word "necessary" in the provisional specification was unfortunate. The question of the use of batteries was then discussed; and Lord Justice Kay said that when you tell a man how to carry out an invention, it does not seem sufficient to state that the size of the batteries should be very large. Lord Justice

Digitized by Google

Lindley said that the circumstances of the case would affect this; and Lord Justice Kay asked, Cannot the batteries be too large? Mr. Lane Fox explained that the batteries could not be too large unless owing to the fact that they were too expensive. He then explained that the number of the cells was proportional to the number of the volts, while the capacity was proportional to the surface of the plates, and the cells should have as large a surface as they could afford to give them. He stated the case of the Plimpton roller skates, in which the sufficiency of the size of a part was discussed, and said that if a workman found that the cells were not large enough he would only make them larger. Lord Justice Kay then quoted from the judgment, where it is said near the end, "There is not a suggestion as to size given excepting that there should be a very large conducting surface." The evidence of Prof. Barrett, Prof. Perry, and Sir F. Bramwell, was then discussed by Mr. Lane Fox, who pointed out that this last witness had stated that the expense was a real drawback to making the plates of as large a size as they might be. Passing then to the sufficiency, Mr. Lane Fox cited "Edison *v.* Holland," where a tar putty filament was described by Edison, but no proportions were given. Many attempts by experts had failed to make this putty, and it was obvious that more skill was required to make tar putty filaments without proper instruction than to adjust the size of a battery to produce regulation. He briefly alluded to the use of switches, and then referred to a remarkable statement by Mr. King, which was quoted in the judgment. He said (*The Electrician*, Vol. XXVIII., p. 581, top of second column), "I will swear that there would be more variation, that is in the voltage in the mains with secondary batteries, than without them. I say the secondary batteries; the current remaining constant tends to cause a variation rather than to diminish it." Mr. Lane Fox had no scruples in saying that this was a deliberate mis-statement of fact. He called attention to the fact that the evidence on his side came from scientific men, but that the witnesses on the other side were commercially interested in the matter. He was confronted by two separate lines of argument. First, that the batteries would act as described, but that the defendants used them for storage; and without switches they could not get enough storage. The second statement was based upon this isolated statement of Mr. King that the batteries were of no use for regulation, and that, on the contrary, they would introduce variation where no variation would otherwise have been. He was astounded at this statement, and was amazed at its appearance in the judgment. It was altogether an isolated statement. He asked Mr. Wallace whether he was prepared to withdraw it, but he (Mr. Wallace) declined to do so.

After quoting some of Sir F. Bramwell's evidence Mr. Lane Fox proceeded to explain the Planté battery, and in order to illustrate its action put in a curve. He specially called their lordships' attention to the fact that with large plates and a small current both the



curves approximated to the static curve. The reason why the defendants' batteries behaved otherwise was because they used their batteries for storage when the engines were not running—a purely commercial consideration. Mr. Lane Fox assumed that his invention had not been anticipated, and based this assumption on the last sentence but one in the judgment, which says that:—"It is not necessary to give any further judgment in this case; but had the plaintiff been able to surmount the above-mentioned difficulties, and had established that by his invention he could have brought about what the Attorney-General said he could, my judgment would have been that his invention was the subject matter of a patent, that it had not been anticipated, and that the defendants had infringed it." Mr. Wallace, however, contended that the Judge had meant that the invention would not have been anticipated if he could have brought about by the invention what he said he could.

The Judges consulted together for some time upon this matter. It appeared that when the Attorney-General made that claim, he claimed too much, and on the other hand, it was not quite clear what Mr. Justice A. L. Smith had meant. It was decided that the Judges would consult Lord Justice Smith upon this matter; and Mr. Lane Fox was told he need not assume at present that his patent had been anticipated.

TUESDAY, JUNE 28TH.

Mr. LANE FOX, continuing his address to the Court, said that the regulating effect of the secondary batteries had been alleged to be incidental only. He cited "Edison *v.* Holland" again to show that the "flashing" process described in the Cheeseborough patent was used in the same way. Lord Justice Kay said that it came to this, the defendants said that regulation was only incidental; but whatever importance was attached to it, if they used it they used it. Mr. Lane Fox added that they not only used it, but derived great advantage from it. The utility in this case, he argued, depended on the commercial value of the regulation, and therefore on the degree of regulation, and cited the Plimpton skate case again to show that even a small degree of utility will do. The whole point of the question of utility was whether they could usefully charge a battery at less than 105 volts. He illustrated the point by reference to the mode of supplying oxygen gas compressed into iron bottles. When a considerable quantity of gas was compressed into such a bottle it was said to be "full," and when the gas had been spent and the pressure reduced to that of the atmosphere, it was said to be "empty;" but this was not really the case. After explaining that he did not require the large amount of storage that was used by the defendants, with the necessary large difference of pressure, Lord Justice Lindley said, "Your point is that a small difference of potential will do." Mr. Lane Fox said that it had been alleged that when working with a small difference of potential the batteries would deteriorate, and added that he had prepared rebutting evidence on that point. A discussion on the subject of rebutting evidence then took place, and the Court said that such evidence could only be brought if some new point were raised which had not been referred to during the plaintiff's case. Mr. Lane Fox said that a new point had been raised, about the damage that a battery might sustain if not fully charged. He contended that the battery as described by him was suitable for the purpose of regulation. He then described Planté's use of his battery, and alluded to the "plateau," or period during which a considerable discharge may be put in or taken out without greatly affecting the difference of potential. In reply to a question by Lord Justice Kay, Mr. Lane Fox said that Planté did not require excessive charging, This was only needed in the later developments of the Planté battery. Excessive charging was necessary for the health of pasted cells, but not for Planté, who clearly stated that it was not necessary to go beyond the bubbling point. Injury had been done to a cell in Mr. Crompton's experiments, where 101 volts were used; but until this experiment was described he did not know that stress would be laid upon this. Mr. Wallace, interposing, pointed out that attention had been called to this injury in cross-examination during the first day of the trial. Mr. Lane Fox drew attention to the evidence of Prof. Barrett, who had used cells for six years with no deterioration, but who was only then just charging his cells, because they had had such a wonderful life. Speaking of the difference of pressure allowed by the Board of Trade, Mr. Lane Fox said that a difference of four per cent. up and four per cent. down was allowed from the normal. Mr. Wallace, interposing, assured the Court that it was two per cent. up and two per cent. down; but Mr. Lane Fox held to the figure which he had given. Some discussion arose as to whether the Crompton-Howell batteries were of the Planté type or no, and Mr. Swinburne's evidence was read, in which he said that "I would not say a Crompton-Howell cell was a Planté."

After reading many extracts from the evidence about regulation being incidental to storage, Lord Justice Kay attempted to lead the plaintiff back to the evidence on the effect of charging at small potential difference, on the health of the batteries; but Mr. Lane Fox did not appear to understand what his Lordship wanted. The question then arose as to the need for always charging up to the point B on Prof. Ayrton's curve; and after a long argument, the point appeared to be cleared up that Mr. Lane Fox held that there was no evidence to support the finding of the Judge that this was always necessary. Mr. Lane Fox thought that Prof. Ayrton's curves might be dismissed, since Mr. Crompton in his evidence had said that these curves did not apply to his batteries. The Court put it to Mr. Lane Fox that the defendant said that he must go to 110 volts in order to discharge at 100 volts: but he replied that the defendants used cells for storage with a thick coating of active material. Lord Justice Kay said that the battery would not be useful unless charged to 100 volts, and that the Judge had been satisfied that this could not be done unless they went to 110 volts in charging. Mr. Lane Fox then described very fully what he meant by a large conducting surface, and said that it meant the surface of the plate which was opposed to the next one. The Crompton-Howell plate being granular or porous had a largely extended action surface, but he drew a clear distinction between this and a conducting surface which was practically the surface of the interposed layer of electrolyte which had to conduct the current. Mr. Wallace challenged this distinction, which he said was not to be found anywhere in the evidence, and disputed the difference between the old and the present Planté cells. Mr. Lane Fox, however, contended that a cell could have a large active surface, useful for storage, without increasing the conducting surface to which he alluded in his specification. After the reading of parts of the evidence of Prof. Barrett, Lord Justice Kay asked some questions in which he appeared to think that volts were a measure of quantity, because the volts rise when a battery is full. He therefore could not understand how the "back volts" could rise to 100 immediately. Mr. Lane Fox did not appear to appreciate his lordship's point, and said that he admitted that 101 volts charge would not do for storage but would do for regulating. Mr. Lane Fox concluded his case a little before three o'clock.

Mr. ROGER WALLACE, in reply, said that Mr. Lane Fox alleged that if Planté batteries had been used by the defendants they would not have had any difficulties in their experiments. He could not attempt to dispose of that point without referring to the evidence. In the specification, page 4, line 5, any battery such as Planté's was mentioned, and all the batteries alluded to in this trial were of that description; the evidence showed, indeed, that the Crompton-Howell batteries approached more nearly to Planté's than any other make. He rejected altogether the distinction between active surface and conducting surface. Mr. Lane Fox had given the Court some very interesting information on this point, but there was nothing about it in the evidence; and this information of his was not evidence. He briefly described the Planté cell, the Faure cell, and the Crompton-Howell cell, which was a reversion to the Planté type. He said that the Planté cell had never been used for large installations, and that commercial work had been done only with the later types. The battery used by Prof. Barrett was not a Planté but

Digitized by Google

an Elwell-Parker battery. It was true that with a slight rise of volts there would be a certain amount of flow, but it would not be a proper charge. In reply to a question by Lord Justice Kay, he admitted that if the mains had a difference of pressure of 100 volts the battery also would have a similar and equal difference of pressure. When Lord Justice Kay remarked that he thus contradicted what he had said before, Mr. Wallace explained that it would take a long time for the battery to do this. It would be of no use. Mr. Crompton had tried to charge a cell with 101 volts, and after 20 hours only a few amperes had passed. Lord Justice Kay: "Never mind the amperes—how many volts?" After some discussion on this misunderstanding, Mr. Wallace continued that in order to get to 100 volts it was necessary to go to 125 volts. Lord Justice Kay said that that was a question of volts and amperes—he knew what these were as well as electricians, because they did not know what they were talking about. Lord Justice Kay asked what voltage would be maintained if the battery were at 100 volts if the volts in the mains dropped.

The question again arose as to the condition of the mains at 100 volts, and the battery at 100 volts also, and Mr. Wallace used as an analogy the diffusion of liquids by osmosis. Lord Justice Kay said that it was no use trying to explain one unintelligible thing by another unintelligible thing. After a reference by Mr. Wallace to the high standing of the witnesses on his side, Lord Justice Lindley said that Mr. Lane Fox had only suggested that his own witnesses were theoretical, and that those of the defendants were interested. Mr. Wallace referred to Prof. Barrett's evidence, and pointed out that it was only a laboratory affair, there being only 10 lamps altogether. Lord Justice Lindley said that it might, for all that, be very important from a patentee's point of view. Mr. Wallace, continuing, said that the evidence did not describe how these batteries were charged, and showed that there was a large excess of battery power. Mr. Drake's evidence was read, showing that no matter how large a cell may be, it must be charged to 125 volts, in order to produce 100 volts. Mr. Swinburne's evidence on Planté cells was then referred to. He had said that Planté plates suffered from waste or leakage; that large plates were not practicable, that there was local action, and the coatings pealed off. Further argument followed on charging, and the fact that secondary batteries had both internal resistance and back volts was alluded to.

The hearing of the appeal was continued on Wednesday and Thursday. A brief account of the proceedings, which consisted chiefly in the reading of the evidence, will be given in our next issue.

The Brush Electrical Engineering Company (Limited) v. Kingsbury.

The following judgment was recently delivered in the Equity Court of New South Wales by Mr. Justice Manning:—This case was very fully discussed before me upon the motion for an interim injunction, which, beyond all question, should have been turned into a motion for decree; and so strongly did I feel, as a matter of fact, that all the materials were before me on the interim injunction motion for coming to a decision that I made the order with costs. Then it was open to the defendant to appeal, which he failed to do; and his appeal, if upheld, would have made him successful in the suit. On that occasion I was asked to give costs as between solicitor and client, and I declined to do so. I cannot imagine any case upon a motion for an interim injunction when such costs would be given, and I mentioned that the question of such costs would be one for the hearing. It seems to me that if ever there was a case for an order as asked for, this is one. Here is a patent which has been established by the decisions of the Court of Appeal in England. Letters of registration were procured in this colony, and the defendant acted for five years as agent for the Company owning those letters of registration. Subsequently there was an assignment to another company, and eventually to the plaintiff Company, and the defendant ceased to be agent. Then that being so, the defendant becomes agent in this colony for lamps which, beyond all question, are an infringement of the patent rights of the plaintiff Company and of those people for whom he had been acting as agent. He admits infringement in the first instance, and appears to have had sufficient knowledge on the subject by paying a royalty for the importation of these very lamps which he says now are not an infringement. He is warned over and over again. I have no doubt that there was a very fair point of law, and it appears to me it would have been a most disastrous thing to have decided that in any other way than the manner in which I decided it on the injunction motion, and there is nothing new to induce me to alter my views. I must treat this case as one in which the only defence set up has been abandoned. I must look at that defence as showing the whole character of the defence to the suit. Edison, having applied for and obtained a grant and patent rights in England early in November, 1879, applies for letters patent out here, and at that time beyond all question nothing whatever in these colonies was known of this discovery; but between that time when by law he was compelled to disclose his invention and the time of his receiving letters patent, there was an account of the invention in the newspapers, by reason of an application made elsewhere, particulars of the invention appearing in the English newspapers, of which copies were published here. This defence is put forward by a man who has been the agent, if not for the plaintiffs, at least for their predecessors in title. Every obstacle has been thrown in the way, even to compelling a commission to be sent to England to prove the incorporation of these companies; it is to my mind as bad a case of infringement of a patent as I have ever heard of, and I think, therefore, upon every ground, that I am bound to make a decree as asked in terms of the first, second, third, fifth and seventh paragraphs of the prayer of the statement of claim. I think, also, it is a very reasonable request that the defendant should make an affidavit within seven days of all the lamps in his possession, control and custody, referred to in the third prayer of the statement of claim; within seven days of the service upon him of notice of a decree having been made in the suit and of this special order, and further that he deliver up all such lamps as come within the description of the third paragraph of the prayer within four days after service of the decree. And I also think that for the purpose of the inquiry as to damages before the Master, he should make a discovery under Rule 122 of all documents which he has or has had in his possession or power within fourteen days after the service of the decree.

Akers and Iliffe.

We are authorised to state that this action, a report of an interlocutory proceeding in which appeared in our issue of June 3, has now been discontinued by the plaintiff, who has withdrawn all claims and charges against the defendant, and has paid him the sum of £1,750.

CORRESPONDENCE.

NEGATIVE RESULTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As a matter of general scientific logic, may I ask on what principle it is assumed that from so-called negative results no certain conclusion can be drawn?

The question arises in connection with an abridged abstract on page 201 of your last issue, and some Notes concerning it on page 184. Suppose that a question to be experimentally examined were whether the earth's gravitative attraction for matter depended on, say, its temperature or its electrical potential; experiment could answer in the affirmative or in the negative, but one answer could be as clear and distinct as the other. There seems to be some ambiguity about this word "negative," because of its two antitheses, "affirmative" and "positive." An answer "no," though a negative reply, may be as decided and *positive* an answer as "yes;" and conclusions may as readily be drawn from the one as from the other. I regard all the negative results of experiments made throughout this century on the connection between ether and matter as being quite as clear and satisfactory as if they had been positive; and I see no reason for desiring one form of answer rather than the other form.—Yours, &c.,

OLIVER J. LODGE.

[Reference is made to this letter in our "Editorial Notes" column.—Ed. *E.*]

MILD STEEL FOR DYNAMO MAGNETS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your review of Dr. Thompson's "Dynamo-Electric Machinery" you suggest that "a word of warning might have been introduced against the use of mild steel both for armature discs and for field-magnets in general cases." As mild steel has been used by dynamo builders for some time now, the warning would in any case have come somewhat late; but, on the principle that it is never too late to mend, will you give us the reason why mild steel should be avoided?—Yours, &c.,

Westminster, June 29, 1892. GISBERT KAPP.

[The whole of that remarkable class of iron which is embraced in the term "mild steel" was not impeached. The word of warning which might have been introduced is that, while charcoal iron is safe, there are many brands of so-called mild steel which are very unsuitable for dynamo construction, as several dynamo makers know to their cost. In special cases, as, for example, in some motors, the residual magnetism of mild steel is useful for field magnets, and the permeability of some brands is so little below that of good soft iron that it pays to use it because it can be more conveniently bought. One brand of mild steel is said to have even higher permeability than good average soft iron, but in many examples of mild steel sheet the hysteresis is serious.—THE REVIEWER.]

CARBON BRUSHES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We have read with great interest the remarks in your last issue regarding carbon brushes. We quite agree with you that, from the absence of carbon brushes at the Crystal Palace, one might naturally come to the conclusion that these brushes were considered of no practical utility by the English dynamo

Digitized by Google

and motor makers; but we can assure you, from our experience, that this is not the case. In America and on the Continent the use of carbon brushes has in the last few years greatly extended, this result being due, in a great measure, to the special composition of carbon we have, after lengthy experiments, arrived at, which has enabled us to offer to the trade brushes which keep the commutator in perfect condition, and which effect also a great economy, as the wear and tear of them is practically nil, and the sparking on the commutator, as you remark, is stopped.

We may say that the greatest enemies of carbon brushes have been those who were the most enthusiastic in their favour when they were first introduced, and the reason is that they cannot be applied to all of the existing dynamos. The nature of the insulation of the commutator and the amount of current which the brush has to carry have to be carefully considered before substituting carbon brushes for copper.

In the majority of cases carbon brushes answer perfectly; but in a few cases they do not adapt themselves at all, or very unfavourably; and through these special cases a feeling of prejudice against carbon brushes has been engendered, which has very much retarded their general adoption, more so than one would suppose.

On the Continent carbon brushes are almost universally used for motors, especially for traction work; and the most important firms have modified the insulation and the length of segments of the commutators of their machines so that they may be enabled to use carbon brushes, of which they recognise the advantages. We know some English firms who are working in the same direction, but who were most likely not ready with their machines at the opening of the Crystal Palace Exhibition.—Yours, &c., C. STREET,

Le Directeur Technique Le Carbone.

Levallois-Perret, June 28, 1892.

SENSITIVENESS OF GALVANOMETERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of June 17th a Paper read by Prof. Ayrton on "Workshop, Ballistic, and other Shielded Galvanometers" is reported. The Paper deals with the performances of recently constructed d'Arsonval galvanometers, and concludes with an example and a comparison. The words are:—"An instrument of this kind, with a coil of 300 ohms, gave 95 divisions per micro ampere;" and "their sensitiveness is, for the same resistance and periodic time, as great as that of Thomson instruments." Lower down we find the periodic time to have been 5 seconds. Particulars are also given as to the size of the divisions, &c. Greatly doubting the accuracy of this statement, I determined to put it to the test. The instrument used was one of Messrs. Elliott's Thomson galvanometers, its resistance being 1,830 ohms. The periodic time was reduced to 4·5 seconds. In Thomson instruments of similar construction their figures of merit are fairly proportional to their resistances. I found that this instrument gave 90 divisions deflection for $\frac{1}{7340000}$ ampere. If the resistance of the galvanometer had been 300 ohms we should have got a deflection of 95 divisions for $\frac{1}{1100000}$ ampere, in round numbers. This, I may add, is about the ordinary performance of a good Thomson galvanometer. Comparing these figures with the results given above, the immense superiority of the Thomson over the d'Arsonval gavanometer (so far as sensitiveness is concerned) is obvious. The statement made concerning the latter instruments is, therefore, utterly misleading, to say the least of it.—Yours, &c., J. W. FLOWER, JUN.

59, Hartham-road, Camden-road, N., June 27, 1892.

ALTERNATE-CURRENT STATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am very much obliged for your Note to my letter of the 6th inst., and also for the letters by Messrs. R C. Jackson, Albert Gay, and James Shepherd, for whose kindness in affording the information contained in the replies I am duly grateful. It is very unfortunate that the poor individuals who are exiled in the provinces should always be told that figures are only given correctly in the Institution *Journal*, and that they should, therefore, be debarred from discussion.

As to parallel running of alternators, there seem to be three sets of plant in this country with which parallel running has been successfully carried out on a practical scale for twelve months or more. These are:—

1. "Ferranti" system. Hick-Hargreave engines. Ferranti alternators. 2,400 volts. 67 ∼. Example: Deptford. Station not run in parallel: Glasgow. Can anyone say how Rochester is worked?

2. "Brush-Victoria" system. Raworth engines. Mordey alternators. 2,000 volts. 100 ∼. Examples: City of London, Bournemouth, Sheffield. Stations not run in parallel: Bath, Chelmsford, Newcastle, Lynmouth, Exeter, Hastings.

3. "Lowrie-Hall-Kolle" system. Fowler engines. Elwell-Parker alternators. 2,000 volts, 70 ∼. Example: West Brompton. Not running in parallel (?): Eastbourne, Brighton.

There are so many cases where parallel running makes all the difference between profit or loss that it is most interesting both technically and scientifically able to ascertain where such method of supply is in use, and if I have been mistaken in any of the above I shall be obliged to anyone who takes the pains to put me right. So far as I am aware, the only other system in use in central-station work to-day and to be continued permanently, is that of Parsons, at Newcastle and District, Forthbanks Stations. On this system, probably parallel running is not such a vital matter, and, therefore, is not attempted. Beyond that we have Thomson Houston at Taunton and Woking, and Kingdon at Weybridge.

I duly read Mr. Gay's article when it appeared, and had seen the station under his charge running in parallel, but the switchboard is so arranged that either "districting" or "paralleling" may be adopted, and I do not think it was well known which practice was in daily use.—Yours, &c.,

44, Hemans-street, Liverpool, CHARLES H. YEAMAN.
June 5, 1892.

SUNSPOTS AND MAGNETIC STORMS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Seeing by a late number that M. Janssen has thrown some doubt on the connection between sunspots and magnetic storms, and suggests waiting for news from the Southern Hemisphere *re* the magnetic storm of February 14th last, I think it as well to inform you that on that day (Sunday) a severe magnetic storm was felt on the telegraph lines both east and west; and the quadruplex lines to Sydney and Adelaide were for some time unworkable. Unfortunately, I was at home and knew nothing of it till next day, when the phenomena were not to be observed, and none of the operators in the chief office made any exact observations. At the same time an enormous sunspot was visible.

Again, on November 18, 1882, a similar magnetic storm was felt both here and in Scotland and Northern Europe at precisely the same time. An E.M.F. of quite 100 volts was visible on the main Sydney line, which was always waxing and waning and reversing. Work was quite suspended from 8 p.m. (when the storm was at its height) till 10:35 p.m.; at that time I believe sunspots were very marked. I enclose a memo from the Government Astronomer in answer to a query.—Yours, &c.,

H. W. JENVEY, Electrician,
Postal Department, Victoria.

General Post Office, Melbourne, Victoria,
Australia, May 18, 1892.

Telegram from Observatory. Melbourne, Victoria,
For Mr. Jenvey.

Magnetic storm commenced Saturday very strong. Continued till yesterday, when disturbance fell off. The immense sunspot is cause.

R. L. J. ELLERY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The connection between the variations of the earth's magnetism and the passage of faculæ and spots over the sun's disc, or, in other words, that there is a correspondence between the periods of maximum magnetic disturbance and those of maximum sunspot intensity, has received additional con-

Digitized by Google

firmation by the recent magnetic disturbance of February 13th and 14th.

Simultaneously with the appearance of earth currents on February 13th, on the European lines, a similar phenomenon was observed on the Indian lines at the Central Telegraph Office, Bombay.

The earth currents began to be first felt on all the lines running S.E. at 10:25 a.m. Madras time, or 5 a.m. Greenwich, they extended to the N. and N.W. lines gradually; the last mentioned continued to be affected till noon of the 14th. They were very variable, and at intervals very strong, particularly on the lines running S.E. The impulses were in both directions, changing rapidly from + to − within a few minutes. Their frequency it was difficult to determine, while the potential was at times much higher than our normal working currents, which on a duplex line is as much as 10 milliamperes. Outgoing traffic on all the lines was much retarded while the disturbance lasted, which was most felt between the hours of 10:25 a.m. and 2:30 p.m. Madras time.

The Madras Railway Company's lines were temporarily interrupted, the signallers complaining of strong left and right deflections.

The Madras-Penang cable, while under test on the 14th, was traversed by an earth current of a strength equal to that which would have been produced by a battery of 25 volts.

On May 18th and 19th strong currents were again observed on the Government and railway lines, but not of that intensity as those of February 13th, the lines running N.N.E. being more affected than any others.

Since the 24th inst. a sunspot has been visible to the naked eye in this locality; it is best observed at sunset at about 7 p.m. (Madras time), and it would appear to have but recently come on the disc (East limb).—Yours, &c.,

Deesa, May 28, 1892. C. P. O'Reilly, Indian Telegraphs.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

Tenders Invited.—The Asylums Committee of the London County Council are prepared to receive tenders for the generating plant and principal mains required for the installation of the electric light at the London County Lunatic Asylum, in course of erection or completion at Claybury (Woodford), Essex. Printed forms of tender, contract (with specification and schedules annexed) and bond, and lithographed copies of the drawings, can be obtained of the Clerk of the Committee at their offices, 40, Craven-street, Strand, on payment of £5 (returnable on a bonâ fide tender being delivered); and tenders must be delivered at the offices of the Committee not later than noon on the 26th inst. Further particulars appear in our advertisement columns.

——— The Committee of the Glasgow Town Council on Gas Supply and Electric Lighting invite tenders for the providing and erecting of (1st) steam engines and pipes; (2nd) dynamos, switchboard, and connections, &c.; and (3rd) arc lamps. Plans and specifications may be seen and forms of tender obtained on application to Alexander B. W. Kennedy, Esq., 19, Little Queen-street, Westminster, or at the Gas Office, 45, John-street, Glasgow. Sealed offers, marked "Tender for Steam Engines and Pipes," or as the case may be, will be received by Sir J. D. Marwick, LL.D., Town Clerk, on or before Tuesday the 12th July.

——— The Art Gallery Committee of Manchester invite suggestions and tenders from electrical engineers as to the best method of illuminating the entrance hall at the Art Gallery, Mosley-street; also for the lighting of the two new galleries with incandescent lamps similar to the system now in use at the present galleries. The various lights are to be supplied from the present dynamos. Particulars may be obtained at the City Surveyor's office, Town Hall, Manchester, where tenders are to be delivered by the 7th inst.

——— The municipal authorities of Mahon, in Spain, will receive tenders until July 14, for the electric lighting of that town.

——— The Spanish Colonial Minister invites tenders for the installation and working of a telephone exchange at Mantanzno, Cuba. The caution money is 400 pesos, and tenders must be in by August 8.

Tenders Accepted.—The Chiswick Local Board have signed an agreement with Messrs. Bourne and Grant for the lighting of the parish by electricity, subject to the approval of the Board of Trade.

——— The City of London Electric Lighting Company (Limited) have accepted the tender of Mr. W. Shurmur for the erection of engine and boiler-house at Meredith Wharf, Bankside, S.E., for the sum of £6,610.

Haiphong, Tonkin.—The Compagnie Continentale Edison have just concluded a contract to instal the electric light at Haiphong.

Vaughan-Sherrin Electrical Engineering Company (Ltd.)—Notice is given by Mr. S. Hedges (liquidator of this Company), of 15, George-street, Mansion House, E.C., that creditors are required to send in their names, addresses, and particulars of their claims to him by the 29th instant.

Messrs. Thomas Barraclough and Co. (Limited).—At a meeting of the shareholders of this Company (carrying on business in Manchester as wire-covering machinery manufacturers), held on June 22nd, it was resolved to wind up the Company; Mr Alfred Tongue, of 44, Brown-street, Manchester, being appointed liquidator.

International Exhibition Association of Electrical Engineering and Inventions, 1890.—All claims against this association are to reach the liquidator, Mr. J. A. Robertson, 33, Charlotte-square, Edinburgh, by to-morrow (Saturday).

Froude-Hurrell Torpedo Company (Limited).—Mr. Justice Vaughan Williams will on Saturday (to-morrow) hear a petition presented by Mr. M. H. Hurrell for the compulsory winding up of this Company.

Excelsior Copper Company (Limited).—A petition is to be heard at the Royal Courts of Justice on July 7th for the compulsory winding up of this Company.

Crystal Palace Exhibition.—The following information has been issued by the Crystal Palace authorities:—"The London, Brighton and South Coast and the London Chatham and Dover Railway Companies have agreed to convey unsold exhibits originally sent from stations on their lines on the return journey free of charge, at owners' risk, on production of a certificate signed by Mr. Henshaw Russell that such exhibits remain the property of the exhibitors. It will be necessary before any certificate will be issued, that a written application be made to Mr. Russell at the Palace, setting forth that the exhibit to be conveyed remains the property of the exhibitor."

Messrs. J. and G. Odhams.—We have received the fourth edition of the illustrated catalogue issued by this firm, containing particulars of the various electrical specialities manufactured or sold by them.

Messrs. J. G. Statter and Co.—This firm have just secured the contract for two electrical cranes for the Southampton Harbour Board, and also for three 23-unit dynamos for the electric light installation at Lord Rothschild's establishment at Tring Park.

The Imperial Institute.—Messrs. Julius Sax and Co. have supplied the whole of the internal telephone exchange system for this Institute. This exchange system is connected with 40 outlying stations.

Roper's Electrical Engineering Company (Limited).—This firm have recently completed a large installation of the electric light at the Alhambra, Hull. A 16-H.P. Tangye gas engine with a 20in. stroke and two 6ft. fly wheels is used. The installation has proved a great success.

Messrs. Trackson Brothers, of Brisbane.—This firm have recently supplied the electric light fittings for the Parliament buildings at Brisbane.

International Exhibition of Building Materials.—An international exhibition of building materials is to be held at Lemberg, Austria, from August 30 to September 20, and the list of exhibits includes telephones, electric bells, and general electric housework.

Another Exhibition.—An exhibition of laundry and domestic appliances is to be held at the Central Hall, Holborn, W.C., in August next, under the management of Messrs. Harry Etherington and Co.

An Electrical Sailing Gig.—We are notified that amongst the latest orders received by Mr. Sergeant is one for an electrical sailing gig for the Norfolk Broads. The boat is to have a specially designed motor, the accumulators used being of the E.P.S. T type, consisting of 19 plates. These are to be placed below the water line. It will be possible to either row, sail, or propel electrically at the will of the owners. The boat is built to accommodate six persons.

International Tariff Changes and Customs Regulations.—The last issue of the *Board of Trade Journal* contains a number of modified Customs tariffs, including those for Sweden, the Niger Territories, and Trinidad. The new duties for Sweden include a reduction of 5 per cent. on the *ad valorem* duty on electro-meters, and an increase of 10 per cent. on the *ad valorem* duty on steam

Digitized by Google

engines, machines, implements, and tools. Leather and other driving belts, cast-iron tubes and pipes, steam engines and boilers (not otherwise specified), are now admitted free. For the Niger Territories all merchandise of an electrical character is admitted free. Under the new Customs tariff of Trinidad, copper, bronze, zinc, and lead articles for domestic and building purposes, india-rubber and gutta-percha goods, telegraph wires, and all electrical instruments and appliances for communication and illumination, steam engines and similar machinery, are free of duty. The same number of the Journal contains particulars of the Treaty of Reciprocity between Guatemala and the United States; materials for electric lighting and materials for the construction of railways and their equipment, are admitted into Guatemala from the United States free of duty.

THE "DAILY CHRONICLE" AND "LLOYD'S NEWSPAPER."—A large gathering of gentlemen interested in the development of rotatory printing machines met at the printing and publishing offices of the *Daily Chronicle* at midnight on Friday last to witness the new machinery installed by Messrs. Hoe and Co. There are eight machines in all, each capable of producing 24,000 copies per hour of the *Daily Chronicle*, including the pasting in of the two-page literary supplement. This is one of the finest sets of rotary machinery for printing purposes to be seen in London, and though somewhat intricate, the progress of the work can be observed by the man in charge of the machine during the whole operation. This is rendered possible by the application of the electric light; several incandescent lamps are installed in each machine, so that the interior of the machine from the time the paper enters to the completion of the work is brilliantly lighted, and the slightest accident to the sheet while travelling can be observed. Those of our readers acquainted with printing machinery will understand how very important this feature is with a machine travelling at the rate of 24,000 copies per hour; in fact, we question whether without the electric light it would be safe to drive the machine at this extreme speed, as but a moment would suffice to choke the machine with spoilt paper if a break in the sheet, or any similar accident, were unobserved by the attendant. The electrical work has been well done by Messrs. Paterson and Cooper.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

10,603. B. M. DRAKE, J. M. GORHAM, W. C. JOHNSON, and S. E. PHILLIPS. London. Improvements in electrical accumulators.

10,609. W. S. SIMPSON. London. The protection of insulating material or cable, line, and like electric wires to preserve the insulating material from atmospheric and other destructive media, and for preventing escape of sound vibrations from telephone wires.

June 4, 1892.

10,632. C. T. P. BRAIN. Liverpool. Improvements in electric switches.

10,651. H. T. SULLY. South Woodford. An improvement in ceiling roses (or fittings) for use with pendant electric light fittings.

10,653. H. HELBERGER. London. Apparatus for automatic calculation of electric gas or water distribution.

10,690. T. PARKER and A. E. ROBINSON. London. Improvements in anodes for use in electric cells for treating chlorides, fluorides, or other compounds, and the like.

10,696. A. SHIELS. London. An improved detector cover for electric push-knobs and the like.

10,706. W. S. SMITH and W. P. GRANVILLE. London. Improvements in effecting electric telegraphic communication, applicable especially for telegraphing to lighthouses, either floating or on rocks, at a distance from the shore, or for telegraphing to and from vessels.

June 7, 1892.

10,715. C. F. JACKSON. London. Improvements in conductors for the distribution of electrical-energy.

10,716. C. R. G. SMYTHE. Glasgow. Improvements in and connected with junctions for electrical conductors.

10,735. H. C. BULL. Liverpool. An improved process and apparatus for making sodium, potassium, and like metals by electric action, and producing ferric chloride as a dry powder.

10,742. R. STEENBERG. Newcastle-on-Tyne. Improvements in or relating to electric telegraphic signals—receiving apparatus.

10,762. E. E. WEAVER and G. B. MANYPENNY. London. Improvements in incandescent electric lamps.

10,777. THE PRINCESS COMPANY (LIMITED). London. Improvements in electric batteries. (The Princess Company (Limited), Mersch.)

10,783. T. CASSON. London. Improvements in electro-pneumatic action for organs.

10,818. C. BOLLÉ. Manchester. Improved electrical insulating conduit. (Charles W. Jefferson. United States.)

June 8, 1892.

10,823. E. W. BULLER. Birmingham. Improvements in the construction and attachments of insulators for telegraph, telephone, and such like purposes.

10,847. R. N. LUCAS, A. J. MAYNE, and A. GEORGE. London. An appliance for actuating an electric transformer switch.

10,850. H. WEYMERSCH. London. Improvements in primary voltaic batteries.

10,855. H. F. KIRKPATRICK-PICARD, and H. THAME. London. Improvements in secondary batteries.

10,870. H. H. LAKE. London. Improvements in electrical measuring instruments. (E. Weston, United States.)

10,873. C. A. MCEVOY. London. Improvements in electrical indicator apparatus.

10,876. J. A. TIMMIS. Westminster. Improvements in the reflection and distribution of the electric light.

June 9, 1892.

10,932. W. J. BIRNIE. London. Improvements in secondary batteries for electric lighting and power.

10,945. A. W. DAVIES and P. R. NUNES. London. An improved electrical advertising device.

June 11, 1892.

11,032. J. T. HARRIS. London. An improvement in insulating supports for electrical conductors led in culverts.

11,038. G. BINSWANGER and H. J. COATES. London. Improvements in electric signalling apparatus.

11,041. V. G. LARONI. London. Improvements in "electrical safety devices."

June 13, 1892.

11,050. D. COOK and E. PAYNE. London. Improvements connected with tubular electric conductors.

11,067. W. A. PERRY. Birmingham. Improvements in and connected with joining the ends of telegraph and of telephone and other wires, and in machines for preparing the said ends of the wires.

11,071. W. SMETHAM. London. Improvements in electrical apparatus for scoring in billiards or other games, applicable also for showing the number of revolutions of marine and other engines, and for other purposes.

11,085. WOODHOUSE AND RAWSON UNITED, Limited. London. Improvements in electrical indicators. (R. Varley, United States.)

11,087. W. L. WISE. London. Improvements in galvanic batteries. (T Rosati, E. Righetti and G. O'Connel, Italy.)

11,096. A. C. MOLL. London. Improvements in or relating to telegraphic instruments.

11,014. H. HAMMARLUND. London. Improvements in telephonic apparatus.

June 14, 1892.

11,119. F. BROADNAX. Liverpool. Improvements in electric switches.

11,126. J. PATERSON. Lancashire. An improved element by the acid of which a current of electricity may be generated.

11,141. J. E. WEYMAN, G. HITCHCOCK and J. A. DRAKE. Sheffield. Improvements in hydrocarbon motors, and in apparatus and appliances connected therewith.

11,147. H. H. LLOYD. London. Improvements in secondary or storage batteries.

11,154. W. P. THOMPSON. Liverpool. Improvements in the method of welding metals electrically. (C. L. Coffin, United States.)

11,181. W. PETCHEY. London. An improved construction of electric alarm clock.

11,192. T. REID. London. Improvements in and relating to the driving of dynamo-electric machines, and in apparatus therefor.

June 15, 1892.

11,194. B. M. DRAKE and J. M. GORHAM. London. Improvements in indicating apparatus for high-tension circuits.

SPECIFICATIONS PUBLISHED.

All Specifications price 8d.

1891.

9,642. WATT. Electric arc lamps.

13,252. FÉRY and DUCRETET. Electrical contact-making and breaking devices.

13,367. SLOPER. Electric telephone switches, &c.

13,802. SOHLMAN. Electric current generator.

14,509. MILLS. Electrical transmission of power.

19,495. POWERS and VAN BUREN. Electrical conduits, &c.

1892.

2,055. WISE (BERTOLINI). Closing electric circuits.

6,181. WOOLLEY. Electric fire alarm.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF LORDS.—THURSDAY, JUNE 23RD.

Select Committee on the Electric Railway Bills.

The Select Committee of the House of Lords, presided over by the Marquis of Waterford, met again to-day, and resumed their consideration of the Baker-street and Waterloo Railway Bill. Sir Benjamin Baker gave evidence as to the interchange to take place between the St. John's Wood branch of the Metropolitan Railway and the new line. The station of the Electric Railway would be constructed under the sidings and at the end of the platform of the existing St. John's Wood Railway. A subway would probably be constructed right across the whole of the lines, and accesses given to it from the lower station communicating with the upper. The interchange would be from the low-level platform of the electric railway to the high-level platform of the St. John's Wood Railway. In the proposal of the electric railway the distance between the two platforms would be 30ft. The Chairman directed that a clause should be inserted in the Bill providing that separate shafts for ventilation, not less than 5ft. in diameter, should be constructed at all the stations. The clauses of the Bill were then gone into, and the Bill ordered to be reported for third reading. The Bill will pass through its final stages in the next Session of Parliament.

FRIDAY, JUNE 24TH.

The Great Northern and City Railway Bill came before a Committee of the House of Lords, presided over by Lord Poltimore, on Friday. The only opponents to the Bill in this House were the Metroplitan Railway Company. After Mr. Greathead, the engineer to the line, had given evidence, Mr. Moon, on behalf of the promoters, submitted to the Committee whether, in view of the favourable report of the Joint Committee of both Houses on the question of electricity as a motive power, they would require evidence on that subject, which elicited from the Chairman a declaration that the Committee were satisfied on that point. Sir Albert Rollit, M.P. for South Islington, expressed the views of his constituents in favour of the line, the district being densely populated, and much in want of railway accommodation. Other local witnesses also gave evidence as to the overcrowding on the North London and Great Northern lines; and Sir Henry Oakley, the General Manager of the Great Northern, confirmed these statements, and said that with the present means it was utterly impossible to cope with the enormous traffic, especially in the morning and evening. The scheme was therefore welcomed by the Great Northern Company, which would run through trains. He was severely cross-examined by Mr. Worsley Taylor as to whether the support accorded by the Great Northern to the scheme was not an abrogation either of the spirit or the letter of an agreement between the Metropolitan and Great Northern Companies, under which the latter already obtained access to Moorgate-street over the former Company's lines, and in respect of which they were bound to pay a minimum sum of £7,000 a year, though the payment in recent years had been as much as £24,000 a year. Mr. Worsley Taylor asked the Committee if they passed the Bill to annex to it conditions providing either for the termination of that agreement or that the Great Northern Company should be bound in future to pay to the Metropolitan Company the amount which they were at present paying. The Committee, after a private consultation, said they were unanimously of opinion that the opponents had failed to make out a case, and passed the Bill.

The Waterloo and City Railway Bill, which will be proceeded with next Session, has been read a second time and committed.

COMPANIES' MEETINGS & REPORTS

West Coast of America Telegraph Company (Limited).

The fifteenth ordinary general meeting of this Company was held last Monday at Winchester House, Old Broad-street, under the presidency of Mr. Henry Roberts.

The SECRETARY (Mr. Fred. L. Robinson) read the notice calling the meeting and the minutes of the last meeting.

The CHAIRMAN then said: Gentlemen, I presume it is your pleasure that the report and accounts be taken as read. Before moving their adoption I wish to take this opportunity of referring to the loss we have sustained by the death of the late Chairman, Mr. Alfred Marshall. He was a gentleman who took a keen interest in the affairs of this Company; and his geographical and commercial knowledge of all the ports and places our cables touch, rendered him invaluable to this Company, and we all deeply deplore his loss. Referring to the report and accounts, the gross earnings, although showing a very large decrease as compared with the previous year, may be regarded as satisfactory when all circumstances are taken into consideration. The year under review was ushered in with the revolution in Chili, which was not terminated until the end of August. The cables of this Company connecting the principal ports of Chili were interfered with by both parties, the war vessels of the Congressionalists cutting the Mollendo-Arica and the Arica-Iquique sections on February 4th, the Iquique-Antofagasta section on February 6th, and the Antofagasta-Caldera section on March 17th. These cables were all repaired between April 17th and May 6th, so soon as the then existing condition of affairs permitted our repairing steamer to do the work. The Mollendo-Arica and Arica-Iquique sections were closed for public traffic by order of the Congressionalists from the 10th to the 24th August, and the stations at Santiago, Valparaiso, and Serena were closed to the public from January 20th to March 19th, and from April 1st to September 1st, by order of the Balmaceda Government. They paid us some compensation for stopping our business until March 18th. With regard to the cutting of our cables, we have preferred a claim for the expenses incurred in effecting the repairs, and this matter is now under the consideration of the Government of Chili. I may mention that all the expenses of these repairs have been charged to the revenue account of last year. The West Coast expenses show a decrease of nearly £3,000 as compared with the previous year, principally due to staff alterations, and partly to the low rate of exchange. The working expenses of the steamer "Retriever" show little alteration; during the year the vessel passed her third survey under the regulations of Lloyds' Committee. The item of £150 in the accounts for the Directors' 5 per cent. on dividends refers to the final dividend of 2s. per share for the year 1890, paid in May, 1891. The London office salaries are slightly increased, in consequence of some clerical work being transferred from Lima to London, by which an actual saving of about £300 per annum is effected. The negotiations with the Brazilian Submarine and the Western and Brazilian Telegraph Companies, conducted under the presidency of Sir John Pender, K.C.M.G., have been brought to a satisfactory termination, resulting in the formation of a new company. The share capital of the Company (£100,000) will be held by the Brazilian Telegraph Companies and this Company. The line being worked for our joint benefit, and connecting, as it will do, the ports of Valparaiso and Buenos Ayres, will give us a connection with the Brazilian Companies and the Eastern Telegraph Company over a line duplicated throughout, and opening up a rapid and efficient service between the West Coast and Europe *vid* Lisbon. The new land line is already in course of construction. In addition to the share capital, one quarter of which will be held by us, there will be an issue of £100,000 Debentures, to which you will have an opportunity of subscribing. Our competitor, the American Company, having acquired, since the 1st January, 1892, the existing land line between Valparaiso and Buenos Ayres, so adjusted the tariffs as to exclude us from participating in any European traffic at our principal stations; and this state of things will continue until the new line is completed, when the public will have the benefit of a service which will carry messages between Europe and the West Coast of South America, entirely over lines owned by English companies, and worked by English operators. It is, of course, impossible to say how far we shall benefit by the new and improved service, but we may at least expect a fair share of the traffic to and from Europe; and this traffic is a growing one. With regard to our earnings during the present year, it has been thought desirable, owing to the competition, not to publish, or issue in any form, the monthly receipts. This course is absolutely necessary for obvious reasons. Before concluding my remarks, I have to express the satisfaction of your Directors at the decision of Mr. J. Denison Pender to allow himself to be nominated at this meeting for election to a seat at the Board; the shareholders will appreciate the weighty considerations involved in this addition to our strength, particularly at the present juncture in our affairs. I now formally propose:—

"*That the report and accounts for the year ended December 31, 1891, now presented, be received and adopted.*"

Mr. FREDERICK WALTERS seconded the motion, which was unanimously adopted.

The CHAIRMAN: The next resolution is one of the most valuable that I have ever had the pleasure of proposing to a meeting. It is as follows:—

"*That Mr. John Denison Pender be elected a Director of the Company.*"

Mr. WALTERS seconded the motion, which was unanimously agreed to.

Mr. T. R. PACE proposed the re-election of the retiring Directors, Mr. Roberts and Mr. Walters. He said he was quite sure that the shareholders, as business men, all felt that those two gentlemen had rendered the Company very great services during a period of extraordinary trial. It was rarely that a business of any kind in one year was subjected to the trials which their Company must have been subjected to last year—a revolution, with, for a long time, absolute ignorance as to when it was going to terminate; the laying of a rival cable, which for a time, apparently, took the whole of their European business from them; and last, but probably not the least, in the midst of all this trouble losing the Chairman. He thought the shareholders would all understand the great services and attention which the Directors must have given during the past year. No doubt, a separate vote of thanks would be passed to them, and therefore he would not say more in proposing their re-election than this—that the shareholders felt glad that, after all the trouble they had experienced in conducting the affairs of the Company, they were still willing to be re-elected. The past year had brought the Company from its position of being almost in a *cul de sac* to a connection with the large English companies, and thus recovering a fair share of the English traffic.

Mr. LAMONT seconded the motion, also referring in appreciative terms to the services which Mr. Roberts and Mr. Walters had rendered.

The resolution was carried unanimously.

Mr. J. TAYLOR said he was sure that all who were connected with the Company would regret that Mr. Weise had been forced, owing to the state of his health, not to seek re election. It would, however, be a satisfaction to the shareholders to know that his place was proposed to be filled up by a member of the same eminent firm. He proposed the following resolution:—

"*That Mr. John Francis Clarke, of Messrs. Turquand, Youngs and Co., be elected auditor for the present year, with a remuneration of 25 guineas.*"

Mr. BICKLEY seconded the motion, which was unanimously adopted.

The SECRETARY afterwards read the notice given in calling the meeting, relating to the consideration of the following resolution:—

"*That the regulations of the Company contained in the Articles of Association be altered in the following manner, viz., by inserting in Article*

Digitized by Google

11, at the end of the third line thereof, the words 'or making purchases in,' and inserting in the fourth line thereof, after the word 'upon,' the words or in.'"

In answer to Mr. TAYLOR,

The SOLICITOR stated that under the Articles of Association, as they stood at present, the Company's powers of investing were too limited. It had already transpired at the meeting that the Company would have to purchase shares in the new Pacific line, and the proposed alteration was mainly suggested by that consideration.

The CHAIRMAN, in further reply, stated that they had not the full powers which they required, and which the passing of the resolution would give them.

Mr. TAYLOR: The alteration will not give the Company power to purchase its own shares?

The CHAIRMAN: We cannot invest our funds in our own shares or debentures.

On the motion of the CHAIRMAN, seconded by Mr. WALTERS, the resolution was unanimously agreed to.

A vote of thanks to the Chairman and to Mr. Walters brought the meeting to a close.

Eastbourne Electric Light Company (Limited).

The annual meeting of this Company was held on the 29th ult., at the Clifton Hotel, Eastbourne, under the presidency of Alderman G. Bourton (the Chairman of the Company).

The Directors' report alluded at length to the agreement with the late managers, which expired on December 31st last, since which date the Directors have resumed their direct charge over the working of the Company. The financial arrangements with the late managers had been settled in the most amicable manner. During the period of working by the managers, they had received and paid everything, so that the Directors had no accounts to submit to the shareholders, but now that they had reassumed control that duty became obligatory on them. Accompanying the report were the accounts for the fifteen months from September 30, 1890, when the Provisional Order obtained by the Company took effect, to December 31, 1891, which showed that a gross profit of £1,950. 0s. 8d. was earned by the Company over and above the working expenses during that period. In order to attract customers for the current, the Directors had decided to reduce the charge per Board of Trade unit from 10d. to 9d., from June 30th; and they hoped that the increase of business would fully compensate the Company for the reduction in lighting rental which this would entail.

The CHAIRMAN, in moving the adoption of the report, gave a *résumé* of the history of the Company from its registration in 1882, and then said that the earnings of the Company in 1886 to September were £1,679, in 1887 £2,263, in 1888 £3,529, in 1889 £4,053, and in 1890 £4,539. The figures included receipts for installations, costs of charges, wiring houses, &c. As to the progress they were making, in December, 1885, they had 725 10 c.p. lamps, 1,800 in 1886, 2,889 in 1887, 3,451 in 1888, 4,555 in 1889, 5,451 in 1890, 6,293 in 1891, and 6,613 in 1892. He thought that in itself showed a very satisfactory total in the working of that Company. In addition to these lamps they had orders for 64 more at present; and he had no doubt, when it became known they proposed to reduce the price from 10d. per unit to 9d., that they would go on increasing the number of lights very rapidly.

The report was adopted; and votes of thanks were accorded to the late managers, Messrs. Harvey, Henderson, and Hammond, and to the Chairman.

Resolutions were also carried—(1) approving and adopting the agreement under which the business had been transferred from the managers to the Company; (2) authorising the creation of a First Mortgage Five per Cent. Debenture Issue of £25,000, payable on or before January 1, 1902; and (3) agreeing that the property of the Company, the goodwill of the business, and the Company's rights and interests under the Provisional Order should be taken at £32,120 on December 31st last, provided that £625 be set apart out of the present cash balance to a renewal fund.

West African Telegraph Company (Limited).

The following is the report of the Directors to the seventh ordinary general meeting, to be held at Winchester House, on Friday, 22nd July, 1892, at 12:30 p.m.:—

The Company's revenue for the twelve months ended 31st December, 1891, amounted to £60,214 5s. 11d., against which £20,883 8s. 5d. is charged for ordinary expenses, £2,213 8s. 3d. for expenditure relating to repairs of cables, &c., and £755 19s. 8d. for income tax, leaving a balance of £36,361 9s. 7d. From this amount is deducted £23,722 8s. 4d. (being for interest on debentures £13,555 15s. and for sinking fund £10,166 13s. 4d.), leaving a balance of £12,639 1s. 3d., out of which the Directors have placed £3,395 9s. 3d. to the general reserve fund.

The shareholders have received for the six months ended 30th June, 1891, an interim dividend amounting to 3s. per share, and the Directors now recommend a final dividend of 5s. per share, making together 4 per cent., free of income tax, for the year ended 31st December, 1891; which, with the appropriation to the general reserve fund of £3,395 9s. 3d., will absorb the balance standing to the credit of the revenue account.

A considerable portion of our income is derived from the guarantee of traffic by the Portuguese Government. Our revenue has been seriously affected by the depreciation of Portuguese currency, a loss of over £6,800 having been made during the year on the remittances between Portugal and England. The Board are, however, endeavouring to have this question settled on a more satisfactory basis.

During the twelve months under review the cables of the Company have continued in good working order. On February last, however, the cable between San-Thomé and Loanda was interrupted, but was promptly repaired by one of the Eastern Company's cable ships, the cost of which will appear in next year's accounts. The Bolamo-Bissao cable was broken on the 21st April last, but as the interruption of this section did not seriously affect our traffic, the Directors deemed it expedient to delay the repair until the arrival of the Eastern Company's cable ship, "John Pender," *en route* for the Cape. The cable is now restored.

A new station-house has been erected at San-Thomé, and also a commodious and well-ventilated building at Grand Bassam; these buildings will greatly add to the comfort and health of our staff there.

The Directors who retire by rotation are Sir John Pender, K.C.M.G., and Robert Kaye Gray, Esq., who, being eligible, offer themselves for re election. The auditors, Messrs. Deloitte, Dever, Griffiths and Co., also offer themselves for re-election.

The Chili Telephone Company (Limited).

The following is the report of the Directors to be presented at the meeting to be held at Winchester House, E.C., on Friday, the 8th inst., at 11 o'clock:—

The Directors regret that the business of the Company during the past year has been less profitable than that of the two previous years. This unfavourable result is due solely to the political and other abnormal calamities which befell the Chilian nation, and affected adversely the affairs of the Company. The civil war in Chili is happily at an end, and the industrial as well as the political position of the country is steadily resuming a more settled and prosperous character. Whilst the affairs of the Company for the past year have suffered from the misfortunes of Chili, there is every indication that they will share largely in the return of the national prosperity.

The income from subscriptions and other sources, which in 1890-1 was $387,110, has fallen for the year 1891-2 to $378,850, showing a deficiency of $8,280, which appears very small when it is remembered that the system of the Company was monopolised by the State, and its use by the public suspended for eight months; whilst the destruction of its poles and lines by the retiring troops of the late President, by extensive incendiary fires, and by a snow-storm, such as has not been known in Chili for a century, delayed the resumption of the ordinary business of the Company. The lines have been gradually, steadily, and as promptly as possible, restored, and the subscribers re-connected with the exchanges; so that the number of subscribers now served is nearly, if not quite, equal to what it was before the Civil War began.

The public disasters before-mentioned have increased the cost of maintenance and operating from $102,234 for 1890-1 to $165,400 for 1891-2 = $63,166. The general expenses have increased from $92,826 to $105,780 = $12,954, in consequence of the larger number of dollars paid to *employés* on account of the greatly reduced value of the dollar. Under the above headings there has been a diminution of revenue of $8,280; with an increase of expenditure of $76,120; and, therefore, a less favourable result in Chili by $84,400.

As the bulk of the increased expenditure has been caused by the revolution, a claim has been made against the Government, of which $115,000 remains unpaid. No part of this sum has been treated as an asset in the Company's accounts; whatever may be hereafter received from the Chilian Government will be credited to future revenue.

The deficiency of profit, shown in paragraphs 5 and 7 of the report, has been further increased by the reduction in the rate of exchange, caused by the unfavourable financial conditions prevailing in Chili, from an average of 24d. to the dollar, in 1890-1, to 19½d. in 1891-2; so that, while the profit has been reduced by $84,400, the result in London has been further lessened by the fall in the value of the dollar. The net result of the working in Chili, in sterling, was in 1890-1, £19,205, and in 1891-2 only £8,746; showing the heavy deficiency of £10,459. The expenses in London have been reduced by £254, and the value of the dollar on March 31, 1892, was more than in March, 1891, by 1d., which improved the balance of revenue, so that, taking all the items touching the transactions out of Chili together, a benefit accrued of £2,837, leaving the net deficiency, as compared with 1890-1, £7,622.

The balance of profit in sterling for the year was £6,067, which, with the balance brought from last year, viz., £14,209, makes £20,276 available for division. As the profits have been used for capital purposes they cannot be divided in cash, but the Directors recommend that deferred warrants be issued for 10 per cent. on the share capital, and that these warrants—at the option of the holders thereof—be accepted by the Company for ordinary shares, which will carry dividend from April 1, 1892.

It will be observed that the capital outlay for the past year was £18,720 14s. 7d. This is due to the construction of new trunk lines, to increased capacity in pole routes during re-construction, and to preparation for connecting additional subscribers with the exchanges, whilst at the same time adding to the efficiency of the telephonic plant throughout the Company's entire system. It is anticipated, however, that such further outlay of capital as may be required will be mainly for the purpose of connecting new subscribers to the system, and thereby augmenting the revenue.

The general manager in Chili has succeeded in securing contracts for ten years with the Government, and, for a like period, with the Municipalities of Santiago and Valparaiso, by which the Company materially strengthens its position.

In accordance with the Articles of Association, Mr. Frank W. Jones retires from the Board of Directors, and, being eligible, offers himself for re-election. The auditor, Mr. Thomas A. Welton, also retires, and offers himself for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

[In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in "The Electrician" Electrical Trades Directory and Handbook, 1892, pages 308-322, &c., &c.]

HIRST AND COMPANY (LIMITED).—This Company was registered with a capital of £5,000, in £1 shares, on the 27th ult.; to acquire, take over as a going concern, and carry on in all its branches, the business of mechanical and electrical engineers, and manufacturers of and dealers in labour-saving appliances, scientific and other instruments and apparatus, now carried on at Croydon, under the style or firm of Hirst and Company.

LONDON ELECTRIC MANUFACTURING COMPANY (LIMITED).—This Company was registered on the 24th ult. with a capital of £10,000, in £1 shares. The objects are to carry on the business of electrical engineers, electricians, engineers and contractors, suppliers of electricity, manufacturers of electrical apparatus, mechanical and chemical engineers, and of producers of light, heat, sound, and power by electricity, galvanism, magnetism or otherwise. The regulations of Table A mainly apply. The subscribers are:—

	Shares.
R. T. Harrison, 1, St. John's-terrace, Highbury-park, N.....	1
G. Shaw, 39, Waddon-old-road, Croydon.....	1
F. Day, 55, Tubbs-road, Harlesden	1
W. G. F. Hunt, R.N., Mickleham, Dorking	1
A. B. Coombs, 57, Clarendon-road, Walthamstow	1
J. S. Hooper, R.N., 11, Comeragh-road, West Kensington, W.	1
A. Barrenger, 40, Wightman-road, Harringay, N.....	1

MEITER SYNDICATE (LIMITED).—This Company has been registered with a capital of £15,000, in £10 shares, to carry into effect an agreement, made June 18, between C. W. Meiter of the one part and C. E. Gudgeon, on behalf of this Company, of the other part, and to carry on business as manufacturers of and dealers in caoutchouc, gum, gutta-percha, &c.

PACIFIC AND EUROPEAN TELEGRAPH COMPANY (LIMITED).—This Company was registered on the 24th ult., with a capital of £100,000, in £10 shares. The objects are to purchase, acquire, construct, or cause to be manufactured, wires and cables of all kinds for the purpose of telegraphs and telephones; to enter into and carry into effect an agreement between the Brazilian Submarine Telegraph Company (Limited), the Western Brazilian Telegraph Company (Limited), the West Coast of America Telegraph Company (Limited), the Pacific and European Telegraph Company (Limited), and Sir John Pender, K.C.M.G., for the construction and maintenance of telegraphic communication between Buenos Ayres, in the Argentine Republic, and Valparaiso and Santiago, both in the Republic of Chili; and to construct, maintain, and work, or to promote any other company to construct, maintain, and work, telegraphs, telephones, electric light works, &c. The subscribers are:—

	Shares.
Sir John Pender, K.C.M.G., 18, Arlington-street, London, S.W.	1
Sir James Anderson, 62, Queen's-gate, London, S.W.	1
Thomas Fuller, 13, Chesterfield-street, London, W.	1
Alex. Wood, Abbey Wood, Belvedere, Kent	1
Lord Richard H. Browne, Reigate, Surrey	1
Richard Collett (Secretary to the Brazilian Submarine Telegraph Co.), 50, Old Broad-street, E.C.	1
R. M. Cunningham (Secretary to the Western and Brazilian Telegraph Co.), 19, Great Winchester-street, E.C.....	1

Each of the following companies, The Brazilian Submarine, the Western and Brazilian, and the West Coast of America Telegraph Companies, shall be entitled from time to time to nominate one Director of this Company for each clear number of 2,300 shares of the original capital of this Company, registered in the name of the nominating Company. The number of Directors is not to be less than three, nor more than five. Share qualification £100 (which may be held as the nominee of any other Company). Remuneration as the Company from time to time determine in general meeting.

BOURNEMOUTH ELECTRICITY COMPANY (LIMITED).—Notice has been given that, at the expiration of three months the name of this Company will, unless cause be shown to the contrary, be struck off the Register, and the Company dissolved. This dissolution is, however, subject to the proviso that the liability (if any) of every Director, managing officer, and member of the Company shall continue, and may be enforced as if the Company had not been dissolved.

ELECTRICAL COAL-CUTTING CONTRACT CORPORATION (LIMITED).—A draft agreement has been entered into by the Woodfield Syndicate (Limited) of the one part, and the above-named Corporation of the other, whereby the vendors sell to the Corporation the patents for Great Britain and Ireland, No. 12,676, No. 14,090, No. 16,623 (all of 1887), No. 1,014 (1888), No. 13,369, No. 14,041, No. 19,039 (1889), No. 536 (1890), No. 1,504 and No. 2,664 (1891); and also the benefit of all future improvements in the said inventions to be made by the vendors, and the benefit of all extensions of the terms and privileges belonging to the said patents. The Corporations further acquire the benefit of all licences granted by the vendors for the working of the said patents, and also the benefit of all contracts and negotiations entered into by the vendors for cutting or mining coal by means of the said inventions. The consideration is £202,000, £20,000 in 4,000 fully paid ordinary shares of £5 each, £100,000 in 20,000 deferred shares of £5 each, £7,000 in cash on the completion of the purchase, and the remaining £75,000 by the payment of certain sums according to the shares issued and the profits obtained. As part of the purchase consideration the vendors have the right to subscribe at par for the 2,000 founders' shares of £1 each. The Corporation agree to grant to Messrs. Goolden and Atkinson a licence to use the inventions Nos. 12,676 and 16,623 (1887) and 536 (1891) for other purposes than coal cutting at a royalty of 2½ per cent. on the net value of the machinery manufactured under the said patents. The purchase to be completed before July 1st, and it before that date 10,000 ordinary shares have not been subscribed for and allotted the agreement may be annulled. Particulars relating to the original Woodfield Syndicate are given in *The Electrician* of May 22, 1891.

"LIGHTNING" (LIMITED).—An agreement, made May 23, 1892, between James Whitehead and the above Company, states that it is agreed that James Whitehead shall sell to the Company all his rights and property in the periodical known as *Lightning*, of which he is the sole registered proprietor, and also the book debts and all subscriptions received by him up to December 31, 1891, in consideration of which the Company pays him £800 in cash and £300 in founders' shares of £1 each.

ELECTRICITY SUPPLY CORPORATION (LIMITED).—An agreement made June 9th between the Corporation and Messrs. A. and S. Gatti, states that whereas by a former agreement between the same parties it was determined that in the event of the whole or any part of the shares and debentures of the Corporation, then about to be offered for public subscription not being subscribed for, Messrs. Gatti should procure such a further sum in shares and debentures to be taken up as would enable the Corporation to discharge their indebtedness to them; and in default the Corporation were to allot to Messrs. Gatti such shares or debentures as would, if taken up at par, discharge such indebtedness; and whereas the subscription list closed on June 1, 1892, at which time 4,711 £5 shares and 93 £100 debentures had been subscribed for, it is therefore determined that the Corporation shall allot to Messrs. Gatti 15,289 shares (numbered 10,001 to 25,289 inclusive) and 353 debentures of £100 each, and that the sum of £110,745, payable in respect of the said shares and debentures, shall be retained by Messrs. Gatti on account of the indebtedness of the Corporation to them. Messrs. Gatti also agree to take up or cause to be taken up £25,400 in debentures for the purpose of providing working capital for the Corporation.

LANCASHIRE ELECTRIC AND ENGINEERING COMPANY (LIMITED).—The annual return of this Company, made up to September 27, 1889, was filed on April 13, 1892. Out of a nominal capital of £20,000, in £5 shares, 375 shares had been taken up, and a call of £2 per share made, resulting in the payment of £580, leaving £170 in arrears. The annual return for 1891, made up to June 21st of that year, was also filed on April 13, 1892. The same number of shares had been taken up and £5 per share called and paid. The annual return for the present year, made up to March 15th, was filed on April 13th, the same number of shares being taken up.

R. C. CUTTING, DOUGLASS AND CO. (LIMITED).—A contract, dated June 13, 1892, between Archibald Douglass and the Company, states that whereas the said Archibald Douglass is the sole proprietor of the business of lightning conductor manufacturers and electrical engineers carried on under the name of "R. C. Cutting, Douglass and Co.," at Wardrobe-chambers, Queen Victoria-street, E.C., and whereas the Company had been formed with a capital of £20,000, in £5 shares, with a view to the acquisition and carrying on of the said business, it is therefore agreed that the said Archibald Douglass shall sell the business to the Company, and that the consideration for the said sale shall be satisfied by the allotment to the said Archibald Douglass or his nominees of 1,979 fully-paid shares of £5 each (numbered 8 to 1,986 inclusive).

T. R. HARDING AND SON (LIMITED).—This Company has been registered with a capital of £54,400, in £10 shares, to acquire the undertaking, as a going concern, of a card, comb, steel pin, and counter manufacturer, now carried on at Leeds, Yorkshire, by T. W. Harding, under the style of T. R. Harding and Son, at the Tower Works.

REUTER'S TELEGRAM COMPANY (LIMITED).—The annual return of this Company, made up to the 15th ult., was filed on the 20th. The Company was registered on February 20, 1865, and now has a capital of £100,000, divided into 12,500 shares of £8 each; 10,802 of these have been taken up, the full amount called, and all calls (£86,416) paid.

CITY NOTES, &c.

CALLS DUE.—*July 1st:* Elmore's French Copper Depositing Company (Limited), 60,000 £10 per Cent. Preference shares of £2 each, 10s. *July 5th:* Johannesburg Lighting Company (Limited), Seven per Cent. Mortgage Debenture Bonds of £50 each, £12. 10s.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended June 26th were £747, as against £697 for the corresponding period of last year, being an increase of £50. The total receipts to date, from January 1st last amount to £20,454, against £19,197 in the corresponding period of 1891, being an increase of £1,257.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company's half-yearly general meeting will take place at Winchester House on Friday, July 22. This Company announce that, subject to final audit, the accounts show, after placing about £68,000 to the reserve fund, a balance available sufficient to pay at the general meeting on July 22nd next, the fixed dividend of 3s. per share, being at the rate of 6 per cent. per annum on the preference shares, less income-tax; and a final payment of 2s. 6d. per

Digitized by Google

share with a bonus of 3s. per share, both free of income-tax, on the ordinary shares, making, with previous payments on account, a total distribution of 6½ per cent. on those shares for the year ended March 31st last. The transfer books of the Company will be closed from the 15th to 22nd July, both days inclusive.—The Liverpool office is now K 13, Exchange-buildings, *vice* H 5, Exchange-buildings, Liverpool.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY (LIMITED).—The Directors of this Company on Wednesday declared an interim dividend, for the quarter ended March 31st last, of 2s. 6d. per share, free of income-tax, payable on the 15th proximo. The Share Register will be closed from the 7th to the 14th proximo, both days included. The coupon on this Company's Five per Cent. Australian Government Subsidy Debentures, due on July 1st, will be paid on and after that date at Messrs. Barclay, Bevan and Co.'s, 54, Lombard-street, E.C. Coupons must be left three clear days for examination.

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS (LIMITED).—The Stock Exchange Committee have ordered the further issue of 8,400 shares, Nos. 41,600 to 50,000, to be quoted in the Official List.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).—The usual half-yearly meeting of this Company will be held at the offices of the Company, 38, Old Broad-street, E.C., on Tuesday, July 12th.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended June 24, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,792.

THE ELECTRICIAN.

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 738.—Vol. XXIX. FRIDAY, JULY 8, 1892. PRICE FOURPENCE. *Annual Subscription (U. K.), 19/6*

NOTES.

The event of the week has been the inauguration of the Tivoli supply station. The current is generated by six 350-H.P. Ganz alternators, driven by Pelton water-wheels, with a fall of about 160ft. Each machine gives 45 amperes at 5,000 volts, and this is conveyed to Rome over a distance of about 22 miles by four copper wires. The Via Porta Pia was illuminated by arc lamps on Monday evening. The machinery was started in the presence of the Minister of Public Works, the Minister of Posts and Telegraphs, and many scientific men. Letters of congratulation from several English electricians were read. A description of the plant at Tivoli, and some details of the line, were given in *The Electrician*, Vol. XXVI., p. 608, in the course of Dr. Fleming's articles on "Alternating-Current Electric Supply Stations."

By failing to attend to the most important and practical condition imposed by the Privy Council in the granting of extension of patents, Mr. Lane Fox has been unable to prolong the period over which the payment of royalties may be spread. This, we understand, would have been in Mr. Lane Fox's opinion a convenience to the infringers, but they apparently did not see the matter in the same light.

The details of damage and disaster caused by the severe series of thunderstorms which broke over the country within a few hours of the Dissolution of Parliament would fill two or three of our pages; but though the provincial papers have abounded with descriptions of damage by lightning, no facts have been published from which any new useful or scientific deductions can be made. We notice that on several occasions mantelpieces have been blown out into rooms, a feature to which we have already called attention in these columns. At the Vienna Theatrical Exhibition, the whole of the glow-lamps are said to have been lit up for an instant.

The interesting extension of Thomson's law of maximum economy which is discussed by Mr. Carter in another column suggests that the many laws with which electricians are familiar are capable of application in much wider spheres than even the physical sciences, and in truth pervade all nature and the moral world. Wherever an active force is partially opposed, Ohm's law may be applied. The number of electors who are induced to vote is proportional to a force of persuasion or conviction, divided by laziness or apathy. Ewing's curve of hysteresis lends itself to an elaborate ethical analogy, in which H becomes good or bad influence according to its sign, and the curve tends to asymptotes of virtue or depravity. Thomson's law of economy is really universal, but, depending as it does upon interest on capital for one of its essential factors, it may be often overlooked in these days when capital is said to be an evil, and interest on it (by a peculiar mode of reasoning) a theft from somebody who has nothing whatever to do with it. If, as we are told, the foundations of English philosophy are only now being laid, these laws, under other and broader names, will perhaps someday be recognised as principles of everyday life.

In the account which we publish in another column of the testing of continuous-current transformers, it will be noticed that the same voltmeters and ammeters were used to measure the power supplied and the power developed after double transformation. This was done with a view of eliminating instrument error; but it should be remembered that the only error which is thus eliminated is in such an one as an erroneous constant. If the voltmeter read 1 per cent. too high throughout the scale, or if it read in volts derived from the B.A. ohm instead of a Board of Trade volt, no error would be introduced into the result; but if the scale were improperly graduated, or if the instrument were otherwise an imperfect one, this method of interchange would not ensure a correct result.

Prof. E. J. Houston has thrown the weight of his authority on the question of the physiological effects of alternating currents of high frequency, and has communicated a short statement to the Franklin Institute on this subject. He says that it is well known that the physiological effects of alternating discharges of but moderate frequency are more severe than are those of steady currents of the same strength; but with still more rapid alternations the physiological effect decreases, until, "at extraordinary high frequencies, all harmful physiological effects practically disappear." He refers to the experiments of Dr. Tatum; but high frequencies were not employed by that gentleman. There have been many experiments in which the voltage has been measured with sufficient accuracy, and it is beyond doubt that with a *given voltage* the physiological effect is diminished with high frequencies. But we have never yet seen any record of trustworthy measurement of rapidly alternating currents in

Digitized by Google

this investigation. In *The Electrician*, Vol. XXVI., p. 644, an abstract of a Paper by Prof. ELIHU THOMSON on the Physiological Effects of Alternating Currents of High Frequency was published; but not a hint was given about the method of measuring such currents. Dr. TATUM, in his experiments of 1890, used a hot-wire ammeter, an instrument in which complete confidence may be placed, since it may be easily calibrated by continuous currents. But he did not go beyond 800 per second.

IN his recent communication Prof. HOUSTON quoted from a lecture by Mr. TESLA, in which he says that he had found that by using ordinary low frequencies the physiological effects of the current required to maintain at a certain degree of brightness a tube 4ft. long produces powerful shocks, whereas with 20,000 alternations per second the tube may be maintained at the same degree of brightness without any effect being felt. But he goes on immediately afterwards to say that this is due principally to the fact that a much smaller difference of potential is required to produce the same light effect, and also to the higher efficiency in the light production. It is obvious, therefore, that the illumination of a given tube to a given brilliancy is no measure of the current; and we will go so far as to say that this experiment is very misleading, or rather that hasty conclusions from it have misled many people.

PROF. HOUSTON goes on to suggest that what has been called the "skin effect," or concentration of rapidly alternating currents in the exterior of conductors, may account for the harmlessness of such discharges; but this might very probably increase rather than diminish the sensation, since a very large proportion of the endings of sensory nerves are in the skin, though it is true that the current might thus avoid the vital organs. "As the frequency of alternation increases," says Prof. HOUSTON, "the body becomes more and more protected, until, when the frequency becomes as great as that of the ether waves which cause sunlight, they would probably produce on the surface of the body the same genial effects as are produced by the light and heat of the sun, with which they are probably identical." But sunlight kills bacteria, possibly because they, or their vital organs if they have any, are so minute that they feel ether waves as shocks. They are about the right size to vibrate mechanically in syntony with the ether undulations, and perhaps this is very unpleasant.

To measure these rapidly alternating currents is almost impossible with any galvanometer, and we wait for some measurements with hot-wire instruments, or with Prof. JONES' thermo-electric method, before we can admit that the physiological effect of a current of given magnitude becomes insignificant if the frequency be very high. No physiologist has yet explained the relation of the current as truly measured in milliamperes, and of the voltage, in physiological effects, or whether a "sawtooth" current is more painful than a "sine current." Medical men are gradually acquainting themselves with the subject, and we hope that some really scientific information will soon be forthcoming. Professional etiquette, of course, strictly forbids them to send communications to "lay" journals, but we will endeavour to place before our readers the pith of any results which may be published elsewhere.

IN our issue of June 3rd we printed a short article by Mr. CARL HERING, the object of which was to show, if possible, that a current of electricity produced a number of magnetic lines proportional to the product of the strength of the current and the length of its path. Our criticisms on that occasion have called forth an interesting reply from Mr. HERING, but we still maintain the accuracy of the statements which his letter questions. The quantity K, to which Mr. HERING alludes, is not constant even for circular coils of different sizes, unless the diameter of the wire bears a constant ratio to the diameter of the circle, and for straight wires K will similarly vary with the diameter of the conductor. Moreover, in all practical cases, the presence of masses of iron so much affects the result, that the consideration of coils with merely air magnetic circuits is of little value. The chief importance of Mr. HERING'S suggested method of calculation is due to the fact that, although it may lead to erroneous results if applied universally, yet in the chief practical cases where it can be used it will yield results in fair accordance with facts. Even here, however, it must be remembered that the effects of an ampere turn round a good magnetic circuit, such as that of a dynamo, is the same whether the wire closely envelopes the iron or is wound round it at some distance away, so that an ampere-foot of wire is less effective for the outer layers of the field-magnet coils than for the inner ones.

AT 5:45 yesterday (Thursday) evening we learn from New York (by the courtesy of the Anglo-American Telegraph Company) that the serious condition of Mr. CYRUS FIELD remains unchanged, and that the end may be expected at any moment.

Lord Kelvin.—The Academy of Sciences at Berlin has conferred one of the first four Helmholtz gold medals upon Lord Kelvin.

Gotha.—This city is about to adopt the electric light. Electric current is also to be supplied for power purposes and for running a tramway here.

Proposed Electric Lighting of the Vatican.—We learn from *L'Elettricita* that it is proposed to light the whole of the Vatican by means of incandescent lamps.

Pfarrkirchen.—The town of Pfarrkirchen in Lower Bavaria is deliberating upon granting a concession for street and private lighting. Water-power is available.

Turin.—A project is on foot for utilising 5,000 H.P. derived from the river Cenischia for electric lighting at Turin. The transmission will probably be effected on the "drehstrom" system.

British Association.—We are requested to announce that on Monday, August 8th, there will be a discussion in Section A of the British Association on a "National Physical Laboratory," to be opened by Dr. Oliver Lodge.

Telegraph Communication with Gilgit completed.—It is reported from Kashmir that the telegraph line from Skardu to Bunji has been constructed; consequently, telegraphic communication with Gilgit by way of the Zojilo Pass is completed.

Digitized by Google

Personal.—Mr. Harry Wilkins, Vestry Clerk of St. James's, who conducted the case of the Vestry at the Electric Lighting Inquiry by Major Marindin in 1889, was called to the bar at the Middle Temple on Wednesday last week.

Proposed Paris Exhibition in 1900.—M. Jules Roche, Minister of Commerce, reported upon the preliminary arrangements for an International Exhibition at Paris in 1900; and in a telegram to *The Times* it is stated that it may now be considered as settled that an Exhibition will be held in that year.

Manx Exhibition.—The Isle of Man Exhibition was opened at Douglas on Monday last by the Governor of the island, in the presence of a large assembly. The buildings have been furnished thoughout with the electric light, supplied by the Brush Electrical Engineering Company.

Paisley.—The Electric Lighting Committee of the Paisley Town Council have obtained tenders from three contractors for high-pressure systems, and three contractors for low-pressure systems, with a view of lighting the compulsory area of supply described in their Provisional Order of last year. The estimates ranged between £22,000 and £33,000.

Chicago Exhibition.—It is intended that the steam machinery at Chicago shall be started on May 1, 1893, by the Marquis de Veragua, a descendant of Columbus. As, however, the Marquis is too old to come to Chicago, he will at a certain hour on the opening day press an electric button in Madrid placed in direct communication by submarine cable with the World's Fair, and by this means will set in motion the steam machinery in Jackson Park.

Institution of Electrical Engineers' Conversazione.—On Friday last week the members of the Institute of Electrical Engineers were received by Prof. and Mrs. Ayrton at the Royal Institute of Painters in Water Colours. About 900 guests were present, the visitors including Prof. Crocker and Mr. W. J. Hammer, of the American Institute of Electrical Engineers. One interesting feature of the occasion was that the Institution this year celebrates its majority.

Nordhausen.—A company is now in course of formation in Berlin having for its object the construction of an electric tramway in Nordhausen, and, further, an electric railway to run *viâ* the Harz to Thale. It is proposed to utilise the water power of the Harz for the generation of electric energy, which will be applied not only to the working of the electric railway, but also to lighting and power purposes in the surrounding districts, conditional upon the necessary permission being obtained from the local authorities.

Budapest.—The Town Council of Budapest, says *Industries*, has definitely resolved to give the concession for the erection of an electric central station to Messrs. Ganz and Co., of that city. The station is to be erected in the Aussere Wartzner Strasse, near the Danube, and about 1¼ miles from the city, and will be on the Zipernowsky-Déri-Blathy transformer system. The plant, which will somewhat resemble that of the International Electricitäts Gesellschaft in that city, will include two alternators of 300 H.P. and 600 H.P. respectively.

Death from Paraffin.—A correspondent writes that it has been estimated that in the United Kingdom alone over 10,000,000 lamps are in use. Mr. Alfred Spencer, of the London County Council, stated at the inquest on the late Lord Romilly that he estimated that there were 300 deaths a year caused in this country by unsafe lamps. Mr. Shean, of the Fire Brigade Association, expressed the opinion that 10 per cent. of fires are caused by paraffin lamps, and Captain Shaw, the former Superintendent of the London Fire Brigade, reported 156 fires in one year caused by the upsetting of lamps in London. It is suggested that there should be a short Act of Parliament compelling every lamp to have affixed to it an automatic extinguisher, as recommended in the reports of Sir Frederick Abel, Mr. Boverton Redwood, and Colonel Majendie.

A Practical Form of Ohm's Law.—An ingenious *memoria technica* has been suggested by Mr. Herbert M. Pilkington, of the Edison Electric Illuminating Company, of Brooklyn, which is shown by the accompanying letters. Every one who has had anything to do with the application of electrical laws has no doubt found it difficult at times to remember even so simple a one as that of Ohm. Of course everyone knows Ohm's law; but somehow, just at the moment when it is most needed, it manages to get twisted around into a state of hopeless confusion. This device is intended as a remedy for all these troubles, and to make the application of the law a matter of the utmost simplicity. The *Electrical World* of New York thinks that the design may be worked up into an appropriate badge that can be worn where it is always at hand; but it might more conveniently, perhaps, be scratched on a vacant spot on a two-foot rule. By merely placing the finger over R one finds $\frac{E}{C}$ staring him in the face. Or, if E is covered, its value C R is plainly seen. Concealing C will bring $\frac{E}{R}$ boldly out.

$$\frac{E}{C R}$$

Telegraphic Statistics.—According to the *Journal Télégraphique*, the European telegraph system comprised 407,080 miles of line at the beginning of 1891. The telegraph mileage for North and South America, the Australian Colonies, and other extra-European countries amounted at the same date to 342,550. Adding to the totals the 145,030 miles of submarine cable, we obtain a grand total of 894,660 miles. The number of telegraph offices open in Europe is 67,465, and outside Europe 31,000; a grand total of 98,465. The number of instruments in use is 101,500 for Europe, and 71,000 for countries outside Europe; a grand total of 172,050. As to telegraphic traffic, the figures relating to it are as below:—

Place.	Number of messages.			Receipts.
	Inland.	International.	Total.	£
European countries	162,996,000	44,599,000	207,595,000	10,210,560
Extra-European countries	75,547,000	12,875,000	88,422,000	10,757,200
	238,543,000	57,474,000	296,017,000	20,967,760

Telephone Statistics.—The following table will be of interest; it is taken from the *Journal Télégraphique*:—

Country.	No. of towns provided with exchanges.	Length of wire in kilometres.	No. of subscribers.	No. of conversations.	Average no. of conversations per diem per subscriber.
Germany ...	260	100,396	59,086	223,852,925	12·6
Italy	*42*	*18,128*	*10,481*	*16,709,000*	*5·*
Japan	2	1,680	560	680,000	4
Austria	42	2,267	1,252	540,000	1·5
„	*11*	*32,511*	*7,659*	*12,437,000*	*5*
Sweden	126	6,722	4,767	8,157,000	5·5

The figures printed in italics relate to private companies.

The Ampere Hour.—Some curious definitions of an ampere hour were given in Court during the Lane Fox appeal last week, and are briefly alluded to in our report of the case. The following is an attempt to give rather more fully the general ideas of these definitions:—An ampere hour is not exactly an ampere or an hour, but it closely resembles both, combining their useful qualities and eliminating their incidental drawbacks. Suppose you have an income of £500 a year, then the number of year-pounds, according to or corresponding to the unit of time, gives you the rate of expenditure, and the sum in one hour therefore corresponds to one ampere, and so the amount is an ampere hour. Another very clear illustration may be taken from a stream of water, which flows at so many gallons per minute, the gallons corresponding, of course, to the amperes; so 500 gallon-minutes—that is, ampere hours per gallon, so to speak—is the total quantity or current which

Digitized by Google

measures the rate of flow in unit time for each gallon-hour per minute. So one hour flows for each gallon or ampere, and corresponds to an ampere per gallon for each hour. That is an ampere hour.

Electrical Underground Railway for Berlin.—In a Paper by Mr. Holle, in the *Verein für Eisenbahnkunde*, a scheme for a railway closely following the design of the City and South London line is described. The project has been put forward by the Allgemeine Elektricitäts Gesellschaft. The trains, running at three-minute intervals, will be about 1,000 yards apart, and 48 trains, consisting of 48 electromotives and 144 carriages, will be running at once. Two power stations with two complete plants each will be erected, and under ordinary circumstances one engine and dynamo of each station will supply current to one of the cross-lines and half the circle line; but the leads will be so arranged that, if necessary, the whole system can be worked from either of the stations at will. There will be a constant pressure of 500 volts, slow-speed motors with varying resistances, and gearing running in oil to diminish friction and noise. The total length of the line is about 30 miles, with an estimated cost of £2,550,000, or £68,500 per mile. The charge for any distance per passenger will be 1·2d, The traffic is estimated at nearly five persons per carriage-mile, or 57,000,000 passengers per annum, with 11,800,000 carriage-miles, or 177,000,000 passenger-miles. This would bring in a total yearly receipt of £285,000, of which £144,000 would be required to defray running expenses.

Proposed Teaching University for London.—The following letter from Prof. A. W. Rücker appeared in *The Times* of Friday last week :—

Some days ago you published suggestions as to the constitution of the proposed Teaching University for London which have the approval of an association largely composed of those who teach in London colleges.

Their main contention is that the present sporadic attempts at supplying London with teaching of a University type have largely failed, and that the time has come when efforts which have hitherto been isolated and independent should be made in concert.

No better illustration of the validity of this contention could be found than in two paragraphs which are inserted, without reference to each other, in this week's *Electrician*.

In the first place we are told that the Corporation of the City of London has declined to contribute further to the support of the City and Guilds Institute for a "year or two." In the second, that the Council of University College find it necessary to increase their electrical laboratories, but are unable to supply the necessary apparatus, and are therefore about to send the hat round.

I do not propose to criticise the action of the Corporation, and I sincerely hope that the appeal of the Council of University College will meet with a ready response. But it is time that the question was clearly put to Londoners, Do they think that this sort of thing is worthy of the capital of the British Empire? The classes at the City and Guilds Institute are most successful; yet the Corporation, which helped to start them, now withdraws support when they are in mid career. Meanwhile, what is practically a rival institution in Gower-street can barely make both ends meet, and is hampered at every step by want of funds.

Could any better proof be desired that independent and competing colleges working in the same town can only obtain from municipal bodies and individuals intermittent, uncertain, and insufficient support?

If London is to have an adequate teaching University it can only be by establishing it on a basis so wide and so strong that individuals, corporations, and State departments shall take the same pride in it that we all take in the British Museum or the National Gallery. This can only be accomplished by a fusion of interests. Those who care more for the advancement of learning and the spread of knowledge than for the machinery by which London has tried, with very partial success, to provide for them in the past cannot be too strongly warned that if we let slip the present opportunity of replacing what is already antiquated by one powerful engine for good, another half-century of ineffective effort may be before us.

Electric Lighting Statistics for Paris.—Four companies are at present engaged in the supply of electricity to the Parisian public, viz., the Compagnie Continentale Edison, the Société Parisienne d'Éclairage et de Force par l'Électricité, M. Popp, and the Société d'Éclairage Électrique du Secteur de la Place Clichy. These four concessionnaires had, of course, to agree to the conditions imposed by the Municipality. Clause 16 of the *cahier des charges* runs as follows:—The grantee will pay the town quarterly during the whole period of its concession—(i.) A rental of 100fr. per annum for each kilometre or fraction of a kilometre length of conduit laid in the sewers or under the pavements; (ii.) Five per cent. of the output for light and power purposes, as ascertained either by the amount of the contracts or by the indications of the meters. In the Budget for the present year the following figures are to be found :—

Ascertained receipts in 1890	Fr. 86,353
Receipts which appeared in the 1891 Budget	Fr.160,000
Estimated receipts for 1892	Fr.318,000

The basis for the estimated receipts for the current year is as follows :—

Concessionnaires.	Kilometric tax (francs).	5% of gross receipts (francs).
Compagnie Continentale Edison	3,200	100,000
Société Parisienne	3,200	100,000
Popp	8,200	50,000
Société de la Place Clichy	3,500	50,000
Total	18,100	300,000

From these items we see that by December 31st next some 181 kilometres, or 112¼ miles, of underground electric mains will have been laid in Paris, and that the gross income of the four Parisian electricity supply companies will probably amount to six million francs, or £240,000. Taking the price of the kilowatt-hour at 1fr., the total estimated output is therefore 6,000,000 kilowatt-hours, which would suffice for about 250,000 8-c.p. 32 watt lamps connected.

Electrical Sub-stations.—In ordinary life conventionality, says *Industries*, is a boon to the majority, because it saves them the trouble of deciding for themselves on nearly all their ordinary actions; but it is a kind of bondage to the thinking man, who is apt to decide things for himself on their merits. He frequently goes wrong, but all progress is due to him alone, all the same. And so it is in electrical engineering. Fashion provides the less competent with a convenient mantle, but it prevents rapid development. Though some of our consulting engineers are men of first-rate ability, the remainder are scarcely capable of developing such things as new schemes of electrical distribution. The small transformers in houses are almost universally supposed to have all-day efficiencies of something well over 90 per cent.; but, though it is well known that, other things being equal, a large transformer is much more efficient than a small one, all kinds of mechanisms are devised for cutting sub-station transformers in and out. That is to say, the greatest attention is given to the cutting in and out in the particular case when it is least necessary. Gas engines with water gas can be made to work with about 1½lb. of coal per horse-power hour. They can be started in a few seconds when required, they need little attendance, and require no boilers and very little labour in connection with the gas producer. It may be said there are no large gas engines. When central stations were first started there were no special steam engines for the work. A few inquiries received by one or two leading gas engine makers would soon lead to the production of large power high-speed machinery. When the gas-engine comes into use the secondary battery will disappear from central stations, and will retire to private houses, or to electric tramcars. In these future days there will also be alternating motors. Whether there will be any customers who want them is another matter, but their existence will silence the cry that direct currents must be employed because of the enormous demand for motive power. There is no law of nature according to which alternating currents must be distributed at 2,000 volts. This is also a fashion; and having regard to the extra cost of insulation it would in many cases be preferable to use much lower pressures. The larger portion of the power will be supplied direct at 200 volts plus the loss in the feeders. The distant parts will alone require transformers and high-pressure feeders. The alternating-current advocate seems unable, however, even to think of a low-pressure system. If he had to supply current to a theatre next door to his station he would no doubt do it at 2,000 volts. To recapitulate, we would suggest that sub-stations with dynamotors ought not to exist, and that an alternating distribution should be used, coupled with batteries or not. Further, that in alternating systems sub-stations should be superseded by feeder transformers, and that banking transformers in sub-stations with automatic switches is unnecessary, and will probably lead to breakdowns and failures.

COMMUTATORS.—I.

BY F. M. WEYMOUTH.

That part of a dynamo which may be said to be next in importance to the armature and magnets is the commutator, or collector, as it is variously termed. For it is here that the current, after having been generated in the armature, is finally collected; and it is from and to this part that it is led away through the outer circuit of lamps and so forth, and brought back again for the renewal of lost energy or potential. On returning into the commutator at one side at minimum potential, the current courses through the armature, and is delivered again at the opposite side of the commutator *changed* to a current of maximum potential: hence the term "commutator," from the Latin *commuto*, to change, or alter entirely.

The object of these present articles, more especially for the benefit of the younger readers, or those to whom electrical work may be new but who may otherwise have had good practical training and experience, is now to consider some of the various forms of commutator that have been brought out; and also some of the points that have to be kept in view when getting out the design for this portion of a dynamo, such as have led more or less to those differences of form to which we allude.

Without pretending that a commutator is to any very great extent intrinsically complicated, it yet would be a mistake to suppose that a design may be just "knocked off out of hand" without much thought. As great an amount of consideration within reason is required in designing a commutator as any other active part of a machine. For we shall find in the course of our investigation, that as in all designing, from that of an ironclad downwards, there are conflicting requirements to be dealt with, both small and great. To these, therefore, and other collateral considerations, we purpose first to give our attention, before viewing any special examples in particular; our remarks, moreover, must be premised by mentioning that we confine ourselves to commutators for close-coiled continuous-current machines, such as those having drum, Gramme, or flat-ring armatures.

As is well known, the essential principle in the construction of a commutator is that of a series of segmental bars, held together on a substructure, insulated therefrom and from one another. This, omitting substructure, is illustrated in Figs. 1 and 2, the upper half of the latter being in section, so as to afford a full side view of one segment. The shoulder *a* represents the lug whereby connection is made with the armature winding, and through which the current runs either way between the winding and the segment. The thick black lines represent insulation. Now it is obviously the first consideration that each bar shall be large enough to carry the whole current without undue heating, and shall continue so after a reasonable amount of wear. It must be of sufficient thickness and depth, and have length enough to allow of a proper number of brushes to take the current off. But another consideration immediately follows, in respect of economy, inasmuch as the segments are usually of either copper, phosphor-bronze, or gun-metal, all of which are expensive materials. Hence, with regard to prime cost alone, it is not desirable to increase the dimensions over much either way. Again, as to the length, this dimension affects the length of the machine as a whole—in particular as to shaft and bedplate. This increases the total weight, and adds to the prime cost in respect of cast iron and steel. The diameter of the shaft would need increasing in due proportion. It also, however, means greater floor-space, or, on board ship, deck room. In the latter case especially, where space is limited, if one over-all dimension can be reduced without adding to another, there is an object in doing so. But this, it will be seen at once, is directly opposed to the already mentioned necessary condition, that there shall be a sufficient length of commutator for the brushes. We shall see later on, when dealing with particular designs, what methods have been adopted to meet this combination of requirements.

Now, the segments, besides being liable to wear from the constant rubbing of the brushes, are also liable to burn away from sparking between them and the brushes, especially if the sparking is such as flies from them to the brushes. This evil, however, is less liable to arise when the commutator is divided into many segments in proportion to the voltage than into a few. A commutator of many segments is thus for this reason desirable; and for the further reason that it would give a steadier current at any given speed, than one with fewer parts. This question, however, is one with which the arrangement of the armature winding as a whole is concerned, inasmuch as there are the same number of segments in a commutator as there are sections in the winding. Now, with an armature wound in many sections for a high potential and a small current, the bars need not be of large section; yet they must be of appreciable size. But especially owing to the number of bars all requiring to be separated by insulation, this latter material, by its accumulation, forms a considerable factor in determining the diameter. Hence it comes about that the commutator will be of large diameter, sometimes nearly equalling that of the armature itself. But there being only a small current to be taken off by the brushes, the bars do not require to be long, and the commutator will be short in proportion to the diameter. It is obvious, however, on the other hand, that with any given speed, and greater consequent peripheral velocity, there will be more wear of both brushes and segments, and greater consumption of energy, due to the friction of the brushes, with a large diameter than a small. But with a low potential, and large current, and small number of segments, the total amount of insulation between the bars will be reduced in proportion, while the length will need to be greater to accommodate those brushes. Hence the length of the commutator will be greater as compared with the diameter, and the latter considerably

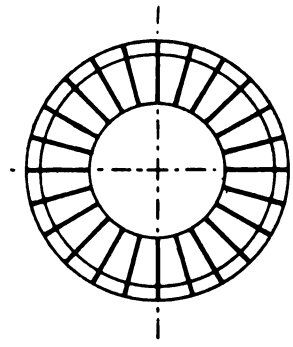

FIG. 1.

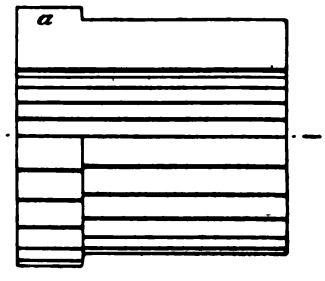

FIG. 2.

less than that of the armature. The thickness of the brushes may, however, be a factor in this question. It is obvious that with any given number of segments the same peripheral brush contact surface subtending any given angle at the centre may be obtained by either having a long thin brush contact surface on a small diameter of commutator, or else a short broad one on a large diameter. Though it is a common feature in small high-tension machines to see the commutator nearly as large in diameter as the armature, a peculiar instance where it is so in the case of a large machine is that of the Elwell-Parker continuous-current transformer, or motor-generator, now on view at the Crystal Palace, and illustrated and described in *The Electrician* for February 26, 1892. Here there are two commutators, one at each end. That receiving the high-tension current for the "motor" function of the machine is composed of a large number of small segments, and the total diameter is nearly equal to that of the armature; while at the same time the length is only a small fraction of the diameter. The other commutator, dealing with the low-potential large current, the outcome of the "generating" function of the machine, has many fewer segments, and is of smaller diameter; while the length is greater than that of the other commutator. Its length is about the same as its diameter, in fact, and a large brush contact surface results. The contact surface being proportional to the current, and not to the potential, much smaller brushes are sufficient on the other commutator.

Returning once more to the subject of sparking and the winding of the armature, it is very necessary that this latter

Digitized by Google

be wound or laid on with symmetry and good workmanship, to reduce this evil generally and the secondary effect of the formation of flats in particular. With regard to drum armature winding, it may, perhaps, be mentioned here that a series of articles on this subject may be found in *The Electrician*, commencing November 7, 1890; also an elementary article on the generation of potential and current in drum winding in *The Electrician* for July 19, 1889, for those readers to whom this matter may still present difficulties. Though sparking has not much to do directly with the form of construction of a commutator, yet as a collateral subject it is so intimately connected that it would seem at least reasonable to touch on it a little fully. Such was, indeed, our original intention. But as at the very first subsequent consideration this has shown itself so expansive a topic to deal with, it has seemed better to leave it for a separate article. The principal bearing this matter has directly on commutator construction, already alluded to, is that it should be subdivided as much as possible. The tendency to spark is thus minimised. But, as will be seen, much subdivision increases the total amount of mica between the bars, and consequently the diameter also. Hence a compromise has to be effected, or at least too much subdivision avoided.

A peculiarity, however, in the wear of the segments, apart from their burning, is that, with wire brushes especially, annular grooves are apt to be cut round the commutator. This is mitigated by allowing the armature a slight end play in the bearings when possible. To equalise the wear also, it is usual to adjust the brushes, when there are more than one in a set, so that the gaps between those in one set do not come opposite the gaps in the other set. For the further reduction of wear and cutting it is commonly the practice to put a very little vaseline on the commutator. This is more necessary, however, when the bars are of soft copper or other metal. When of good hard metal, and with stencil-plate or gauze brushes, it appears to cause no detriment to run dry, without any lubrication. Though under certain circumstances some oils may act as perfect insulators, better even than air, it is not desirable to let the oil from the bearings creep over or into the commutator. With large difference of potential between the segments and the parts of the machine at zero potential, a streak of oil between would carbonise; and carbon being a conductor, a short circuit would be set up, leading to leakage. To prevent this, among other reasons, a ridge is generally turned on the shaft, or on one of the nuts retaining the commutator, or elsewhere, from which the waste oil from the bearing is flung off, and is caught by an overhanging annular hood, or oil-catcher, projecting from the bearing, from which it is drained away.

As to the metal used for the segments, besides the gunmetal, phosphor-bronze or copper already mentioned, iron is sometimes used. The prevailing tendency is perhaps towards copper, though this somewhat depends on the form of the segment. Copper segments may either be cast, which can be done by alloying with a little silver—a method adopted by Messrs. Crompton and Co.—or else they can be rolled to the required segmental section and so be cut off in lengths. This metal is, of course, a better conductor than either phosphor-bronze, or gunmetal, or iron. The copper, when not cast, may be either hard rolled or else annealed. The former would be more durable; but the latter is better as regards conductivity. As, however, the ratio of the specific resistances of hard-drawn and annealed copper is given only as 1,652 to 1,615, this seems so slight in proportion that the question of durability would have more weight, and so the hard copper be preferable.

In the process of construction, these bars are filed, or otherwise worked up true, on their flat sides; then, with thin sheets of mica, usually about one thirty-second of an inch thick, and shellac or other varnish between them, they are all clamped together so as to form a hollow cylinder, as shown in Figs. 1 and 2. According to varying practice, the inside may or may not be bored. But while still clamped together they are put in the lathe, and the ends carefully turned to gauge. The substructure consists of a sleeve or bush, usually of gunmetal, though sometimes when large of cast iron. Over this the cylinder of segments is fitted with insulation between, and fastened on by a nut and washer. These latter are either wrought iron or gunmetal, or may be of steel. The whole now forming a compact structure by itself, the clamps are removed. Put in the lathe once more, the outside is carefully turned to a smooth bright surface. Though we shall deal with variations later on, commutators of this general type such as we are discussing have thus this characteristic in common, that when once built they are complete in themselves, and as such can be put on or off the shaft of the dynamo.

(To be continued.)

ARC LAMPS.*

The steadiness of the light is dependent both upon the efficiency of the mechanism of the lamp, by means of which the carbons are fed together, which must be exactly at the same rate that they are consumed; and on the quality and homogeneous nature of the carbons used. The amount of light depends upon the rate at which energy is transformed at the arc into heat and light.

Efficiency.

The power or number of watts utilised in the arc is always less than the total amount supplied to the lamp, part being used in electro-magnets or solenoids for operating the mechanism, and part being lost owing to the resistance of the carbons.

If W = total power supplied at terminals of lamp,
w = power used in arc,
C = current between lamp terminals,
C_1 = current in series coils,
C_2 = current in shunt coils,
E = potential difference between lamp terminals,
e = potential difference of arc,
R = resistance of carbons,
R_1 = controlling resistance for parallel lamps,
r_1 = resistance of series coils,
r_2 = resistance of shunt coils;

Series Lamp.—Watts lost in series coils $= C_1^2 r_1$,
" " shunt " $= C_2^2 r^2$,
" " carbons $= C_1^2 R$.

$w = e C_1$,
$W = E C$;

$$\text{Efficiency} = \frac{w}{W} = \frac{e C_1}{E C} = \frac{e C_1}{C_1^2 (R + r_1) + C_2^2 r_2 + e C_1}$$

Parallel Lamp.—Watts lost in series coils $= C^2 r_1$.
" " carbons $= C^2 R$.
" " controlling resistance $= C^2 R_1$.

$w = e C$,
$W = E C$.

$$\text{Efficiency} = \frac{w}{W} = \frac{e C}{E C} = \frac{e C}{C^2 (R + r_1 + R_1) + e C}.$$

e and E may be easily determined by use of a voltmeter.

Resistance.

The resistance of carbons, 11 to 15mm. diameter, plain, varies from 0·15 to 0·2 ohm per foot, or, if coated metallically, 0·001 to 0·09 ohm per foot. Cored carbons have a higher resistance than solid carbons. The combined resistance of the carbons of a 50-lamp series circuit (10 amperes) may be 25 ohms greater, or require 250 volts more when newly trimmed than when the carbons are nearly used up.

Resistance of the series coils differs in different lamps. It may be 0·05 to 0·2 ohm and that of the shunt coils 200 to 500 ohms.

Resistance of the arc is made up of two factors, one the overcoming of the back E.M.F. which is constant, the other the resistance of the arc or flame itself. The back E.M.F. is due to the energy required to volatilise the carbon, and for

* All rights reserved. From a forthcoming work by Messrs. Geipel and Kilgour. (*The Electrician* Printing and Publishing Company.)

Digitized by Google

continuous currents is generally about 39 volts; with very short arcs and large carbons it may be as low as 25 volts. The total E.M.F. of the arc may be expressed as $E = e + b\,L$, where e is the back E.M.F. of the arc, b a co-efficient, and L the length of the arc. If L is in millimetres and $e = 39$ volts, then E may be $= 39 + 1{\cdot}8\,L$.

The resistance of normal arcs of 4 amperes may be about 11 ohms; 10 amperes, about 4·5 ohms; and 100 amperes, about 0·45 ohm. The difference of potential of the arc does not appear to increase with the current density, which may be partly due to the increased sectional area of the arc itself, and partly to the increased conductivity of the arc due to the resulting higher temperature.

Beiblätter says for an arc burning silently the E.M.F. is 39 volts, and when hissing 15 volts. No difference is noticeable whether the upper or lower carbon is the positive one. Mixing borax and soda, &c., with the carbon, reduces the E.M.F. to 9 or 10 volts. Intense heating of the positive carbon, produced by surrounding it with a fire-clay jacket, increases the E.M.F. to 47 volts silent, and 21 volts hissing. Cooling the upper carbon by a current of water reduces the E.M.F. to 12 and 5 volts respectively.

Heat developed by Arc.

If H = heat in gramme Centigrade degrees,
E = potential difference of arc in volts,
C = current in amperes,
T = time in seconds;

$$H = {\cdot}24\,E\,C\,T.$$

The temperature of the light-emitting surface of the carbon is that of the volatilisation point of carbon, and is therefore constant, and cannot be raised above that point under ordinary atmospheric pressure. Dewar gives the temperature of the arc at 6,000°C, that is, thrice the temperature of the oxy-hydrogen flame. Rosetti found the positive carbon 3,200°C., and the negative carbon 2,500°C. The temperature of the sun is given as 10,000°C., Rosetti; 250,000°F., Secchi; 4,000,000 to 5,000,00 °F., Ericsson.

The carbon within the crater is in a plastic condition due to the high temperature. The larger the current the greater the light given per unit of power.

Hissing, sputtering, flaming, and general unsteadiness are defects in the arc. Hissing is due to too short an arc, or to use of a carbon with too coarse a grain. Sputtering may arise from impurities in the carbons. Flaming is due to too long an arc, or impurity or insufficient baking of the carbon.

Carbons of too large a diameter, as are sometimes used to prolong the hours of burning, reduce the candle-power obtained per unit of power, and the same applies to the use of very hard and dense carbons. For arcs below 5 amperes the carbons are too small for use in practice, and very large current arcs are difficult to regulate owing to their instability. Soft-cored carbons locate the arc centrally, and give steadier lighting than solid carbons.

With 10 amperes the separation of carbons varies from $\frac{1}{16}$ to $\frac{1}{10}$in. or more. Smaller currents require less separation, larger currents more.

Parallel Working.

For parallel working there should be 60 volts available at least, but 65 volts gives better results, and as much as 70 volts is used in some cases. For a 10-ampere lamp, where the arc requires say 45 volts and the regulating mechanism and carbons 5 volts, this controlling resistance must account for 15 volts, or have a resistance of 1·5 ohms when 65 volts is used. For a 5-ampere lamp it would be 3 ohms, and for a 15-ampere lamp 0·75 ohm. This resistance may be made up of one or more coils of platinoid wire; iron wire is objectionable, owing to its high temperature coefficient.

When lamps are run in parallel with alternating currents the controlling resistance is replaced by an impedance coil, and 50 volts (effective) is sufficient, the arc requiring from 35 to 40 volts only, while the impedance coil has a greater steadying effect than a simple resistance. Thus for the same expenditure of energy a larger current may be used in alternate parallel working, in fact, 13 amperes alternating represents the same energy, viz., 650 watts, as in 10 amperes continuous arcs. It is to be remembered, however, that while the majority of the light in continuous arcs is thrown downwards from the crater, with alternate arcs it it is not. Reflectors should, if possible, be used with alternate arcs. The metallic parts of the solenoids or magnets for alternating lamps must be carefully laminated.

Candle-Power.

The candle-power of arc lamps varies according to the angle at which the measurement is made. The maximum is obtained at an angle of 40deg. to 60deg with the horizontal, and opposite to the positive or top carbon with continuous currents. The horizontal intensity is less than half of the maximum, which, under the most favourable circumstances, without passing through a globe, may be 2,000 c.p. for a current of 10 amperes, using 11-mm. carbons, and the horizontal light in that case would be less than 1,000 c.p.

If S = mean spherical intensity of light,
H = horizontal " "
M = maximum " "

$$S = \frac{H}{2} + \frac{M}{4}.$$

A well-formed crater with the arc or flame confined thereto is the desideratum. With very long arcs the crater disappears, and the ends become rounded. The light emitted from the vapour or flame is comparatively feeble.

Arc lamps (15 amperes) used in the streets of Berlin give 500 to 650 effective candle-power with globes on; they are placed 26ft. 8in. high and 137ft. apart. The light necessary for reading, viz., 10 candles at 40in., is obtained at a distance of 53ft. from the lamp, and in the intervals 4½ candles at 40in. is obtained.

Globes of clear glass absorb 10 to 20 per cent. of light; ground glass, 30 to 40 per cent.; heavily ground glass, 40 to 50 per cent.; and heavy opal glass, 50 to 60 per cent.

Duration and Composition of Carbons.

Lasting power of carbons for a current of given strength varies directly as the diameter. When top and bottom carbons are of same diameter the + wears about twice as fast as the −. With 10 amperes, using 11-mm. carbons, 1 foot of + and 6in. of −, carbon, including allowance for waste, should last 8 hours. Large carbons have more lasting power, and give steadier but less light per watt. Small carbons give more light per watt, but burn away quicker, while the crater is not good. The crater reflects most light when the axis of − carbon is in line with edge of the + carbon. In projectors or search-lamps the carbons are thus arranged:—

Sizes of Carbons Recommended for Various Currents using Cored Top and Solid Bottom Carbons.

Current in amperes.	Diameter of cored positives.	Diameter of solid negatives.
	m/m.	m/m.
5 and 6.	9	9
8	11	9
10	13	11
15	15	13
20	18	15
30	20	18
50	25	20
80	30	25
100	35	30
140	42	35
170	50	42
200	60	50

Carré's carbons are made of pure coke finely powdered, 15 parts; calcined lamp black, 5 parts; special syrup, 7 to 8 parts; the mixture is well combined, and 1 to 3 parts of water are added, and the paste is forced through a die by pressure, and baked in a crucible under a layer of powdered coke and sand.

THOMSON'S LAW OF ECONOMY.

BY E. T. CARTER.

Every electrical engineer is familiar with the law of economy in electric power conductors enunciated by Lord Kelvin, and known as Thomson's law. By means of it the best section to give any cable can be calculated, the extra cost involved by the addition of another pound of copper and the saving of power caused by its addition being all the data necessary to the calculation. It is not, perhaps, so generally known that this law is much more far-reaching in its influence than is involved in its special application to power cables. Not only in the cable, not only for electric power, but wherever power is transmitted or transformed this same law of economy is in operation. Apart from questions of strength, successful design of every form of engineering machinery depends upon the proper recognition of the relationship—the antagonism, as it were—between prime cost and working costs which is expressed by the terms of this law. If we diminish the prime cost we must expect to get an increase in the working costs; and there is a particular value for the prime cost, at which the annual expenses, together with the interest on the prime cost, will be a minimum. Such is the law; and it is eminently a shareholder's law. No engineer can afford to disregard it; but, whether he is designing dynamos and motors, turbines and waterwheels, or steam engines and boilers, he must take it into account.

With electric power cables we have accurate data enabling us to put the law into exact mathematical form; but in many cases the coefficients are wanting, and only a general application of the principle is possible. Yet experience supplies what abstract mathematics is unable to afford, and indicates the most economical conditions in each particular design. With experience, however, a more elastic range of practice is found than would be permitted by an exact knowledge of the coefficients in each case. Let us glance at some of the instances in which an electrical engineer is concerned with the operation of this law. To begin with, it enters into the consideration of the size of the boiler plant, with the flues and chimney attached to it. If we spend more money on bricks and labour and put up a higher chimney, we shall increase the furnace draught and burn more fuel on each square foot of grate. A higher temperature in the earlier parts of the flues results, and a corresponding improvement in the evaporative efficiency. The annual coal bill is reduced by the extra few feet of chimney. But there is a limit to this practice, beyond which it ceases to be economical; for the extra load of bricks and the labour of building it become more expensive than the coal which is saved, while the increased furnace temperature results in more rapid deterioration of the boiler plates. Experience has fixed the economical limit to the height of the chimney for any given size and type of boiler plant. Again, by allowing the furnace gases to escape at a higher temperature, we can get along with a shorter and cheaper chimney without reducing the draught. The boilers will require less heating surface per horse-power, and will therefore be smaller and contain less metal. This economy in the chimney, the boilers and the space for the boilers to stand on, is met by an increase in the working costs; for more heat is thrown up the chimney, the evaporative efficiency of the fuel is lowered, and the coal bill swells to alarming dimensions. There is a particular temperature at which it is most economical to send the gases up the chimney, and long experience has shown that if no economiser is used the gases should escape at about 600° F., while if an economiser is employed we may cool them to about 400° F. Whether we use an economiser or not should be determined by similar considerations. The cost of the economiser, and of the extra feet of chimney it will involve on account of its flue friction, must be set off against the saving in fuel and the reduction in boiler depreciation and repairs—owing to hot-feed—which it involves. In either case it is found to be false economy to reduce the boiler-heating surface below 3½ sq. ft. for each pound of coal burned per hour, when chimney draught is used.

The boiler steam pressure is regulated by this law, *i.e.*, there is a limit beyond which an increase of pressure is actually wasteful. With increased pressure the efficiency of the steam engine is increased, but that of a given type of boiler is lowered, while the prime cost of both is increased. For, with higher pressures, thicker boiler plates are necessary for both internal and external heating surfaces, and the thermal conductivity of these surfaces is lowered. Either, therefore, the heating surface must be very much increased, making the boiler more expensive, or the efficiency will be very much reduced. In the steam engine a higher pressure involves a higher ratio of expansion if the steam is to be used economically; and this cannot be carried out in one cylinder beyond a certain limit, without cancelling its advantage by the rapid liquefaction which occurs at every stroke. High pressures therefore involve compound, triple and quadruple expansion engines, which are primarily more expensive, per horse-power, than single cylinder engines.

Similar conflicting conditions regulate the point of cut-off, and the piston speed of single cylinder or other engines. If we permit an earlier cut-off of steam we shall, up to a certain point, increase the economy of the engine; but we shall also diminish the work done at each stroke, rendering it necessary to build a larger engine in order to get the same horse-power as before. We do not, therefore, set our engines to work at the highest practicable ratio of expansion when they are doing their ordinary load, but at some lower ratio; thus sacrificing a small increment in steam economy in order that the size and cost of the engine may not be inordinately large. An engine supplied with steam at 60lb., and working with a condenser pressure of 5lb., could, if steam-jacketed, work at a ratio of expansion of from 6 to 8 without serious liquefaction. But it would not pay to set the valves at such an early point of cut-off for the ordinary load, for the horse-power would be so low that the prime cost per horse-power would be much too high a figure. We may attempt to reduce the size and cost of the engine by increasing the piston speed, thus allowing of an earlier cut-off by means of a greater number of strokes per minute. For it is evident that if an earlier cut-off reduces the work of each stroke the horse-power may be kept up to its former value by increasing the number of strokes per minute. The prime cost economy of high-speed engines is to be set off against three sources of increased working cost, thus fixing the limit to economical high speeds. Firstly, with rapid expansion there is excessive liquefaction in the cylinder. Steam expanded rapidly expands almost adiabatically, the jacket having little or no time to supply heat to the cylinder steam. Now, the adiabatic expansion of a saturated vapour is necessarily accompanied with partial liquefaction of that vapour, some of it giving up its latent heat in order that the rest may remain saturated while work is being done on the piston. It is unnecessary to enlarge on the fact that liquefaction in the cylinder is both wasteful and troublesome; and most of the re-evaporation that does take place usually occurs in the back stroke, where it causes a wasteful rise in the back pressure. Secondly, increased piston speed causes increased loss of power, owing to the friction at piston rings, glands, &c. Thirdly, it is more than probable that high piston speeds involve a high rate of depreciation of the machinery; and this is more especially the case where the stroke is short and a high piston speed is produced by a large number of revolutions per minute. Against these considerations, however, the electrical engineer must set off the fact that with high-speed engines, making a large number of revolutions per minute, no wasteful and expensive intermediate gearing is necessary in order that they may run high-speed dynamos. It is probable that a better solution of the problem would be found in the abandonment of high-speed dynamos, *i.e.*, by the substitution of dynamos in which a high peripheral speed of the conductors on the armature is obtained without a very great number of revolutions per minute. The economy of material in dynamos is not a question of a high rate of revolution of the armature, but of high linear velocity of the armature conductors.

These few illustrations may serve to show the importance of the law of economy as a law of engineering design. A little consideration will enable one to see that the question whether one shall add another pound of copper to the cable or dynamo, another load of bricks to the chimney, another cwt. of cast-

Digitized by Google

iron to the engine, or another foot to the diameter of the waterwheel or turbine, is, as far as economical considerations are concerned, determined by the opposite consideration, whether the cost of the addition will exceed the capital value of the saving in annual expenses. In other words, *the most economical design in any case is that in which the annual interest on the cost of a small increment of material is just equal to the saving in annual expenses which would result from that small increment.*

It must not be forgotten, however, that economy is not the only consideration. If copper were very much dearer than at present, and coal very much cheaper, the economical current density for a power cable, as given by Thomson's law, would be sufficient to make the conductor dangerously hot and perhaps to fuse it. In every case, therefore, the question of economy must be modified by the essential questions of strength and safety. Consistently with the maintenance of a high factor of safety, there are few problems in engineering which cannot be settled on the basis of this law.

THE ELECTRIC LIGHT INSTALLATION RULES OF THE CHAMBRE SYNDICALE DES INDUSTRIES ELECTRIQUES.

This latest addition to the numerous rules which have been issued for the guidance of contractors retains several useless regulations and one or two very vaguely worded ones. We publish it rather to show what is being done on the Continent than as an example of a valuable set of rules. The old-fashioned rule No. 1 is a relic of the days when fall of volts was not specified. The minimum conductivity is low enough indeed; but we cannot see why a contractor should not use bronze or iron wire if he likes, so long as he does not introduce more than a 2 or 3 per cent. drop.

I.—*Quality of Material.*

1. All wires and cables to be of copper, having a conductivity of at least 90 per cent. of that of pure copper.*

2. Their section must be determined by the condition that the fall of volts between the service box and the most distant lamp is not to exceed 3 per cent. of the voltage at the service box. They are, moreover, to be of such a size that the accidental passage of double the normal current shall not warm them up more than 40°C. This result will in general be obtained if the current density does not exceed

3	amperes	per	sq. mm.	for wires of	1 to 5	sq. mm.
2	,,	,,	,,	,,	5 to 20	,,
1	,,	,,	,,	,,	over 50	,,

Finally, no conductor is to be employed of which the core consists of a single wire having a diameter less than 0·9mm.†

3. The use of bare wires, forbidden as a rule, may be allowed in special cases. Whatever the nature of the location may be, either the insulating coating of the wire or the mechanical protecting sheath must be impervious.

4. Insulation must be obtained by one or more layers of non-conducting materials placed directly upon the copper core. This covering must be sufficiently strong to stand handling when being installed.

5. *Mechanical Protection.*—As a general rule wires are always to be provided with mechanical protection independent of their insulating covering. If conductors are laid along walls in damp places, the mechanical protection must be impervious. Wood casing may be used in dry places. The casing must be of dry wood, and provided with covers. When wires are allowed to remain open to view in dry places, which must as much as possible only be the case when they are beyond reach, they must be protected by ribbon, braiding, or some other covering independent of the insulating material.

6. *Switches.*—The material composing the bases of switches must be appropriate to the nature of the locality. Switches must make good contact, and must not heat when the current is passing. When the breaking of the circuit may give rise to an appreciable arc, for instance, 5 amperes at 100 volts, the apparatus must not remain in an intermediate position, and its base must be of incombustible and unbreakable material.

7. *Cut-outs and Fuses.*—Cut-outs must be arranged so that the fusing of a plug will not give rise to a short circuit. Fuses must be easy to replace, and not give rise to any spluttering of molten metal. They must be clearly marked with a number representing the normal current for which they are intended. They should fuse for a current equal at the most to three times the normal.

8. *Arc Lamps.*—Arc lamps are always to be provided with a covering and a cinder holder. Lamps exposed to the weather are to have their terminals well protected from the rain and from blows. Rheostats are to be mounted on incombustible non-hygroscopic bases. Wires are to be such as not to exceed a temperature of 200°C. under normal conditions of working.

II.—*Conditions for Laying Down Installations.*

9. *Conductors.*—Casings which serve as a mechanical protection to the conductors should not exhibit any discontinuity at joints or sharp angles. Conductors are only to be kept in them by means of the cover. Two wires are not to be laid in the same groove. When crossing gas pipes there must be additional insulation and mechanical protection. When passing through walls and ceilings, the mechanical protection should preferably take the shape of a hard tube with rounded angles. If this tube is metallic a supplementary insulating sheath should surround the wire and project beyond the ends of the tube. When separate conductors are visible they must be at least one centimetre apart, and fixed, so as to keep this distance.

10. *Double Wires.*—Double conductors having within one and the same braiding or covering two separately insulated wires may be used; but the electrical insulation of the two cores, and their distance apart, must be thoroughly well assured. This rule is equally applicable to conductors of the same polarity.

11. *Flexible Wires.*—Flexible wires are only to be used when they are inevitable. They are to be joined up to the apparatus in such a manner that the insulation of the wires cannot be torn off. They are to be connected up to thick wires by means of carefully-soldered joints. A fuse wire is to be placed at one of the points of connection between a flexible wire and the two main conductors.

12. *Soldered Joints.*—Soldered joints are to be done without the use of corrosive liquid substances. They should not form weak points, either mechanically or electrically, and the electrical insulation must be restored with insulating materials equivalent to those which form the covering of the cables or wires.

13. *Switchboards and Auxiliary Apparatus.*—It is always desirable that circuits should branch off from switchboards, subdivided as far as possible. These switchboards are to be kept well away from the walls, and the wires and cables are as far as possible to be joined up on the front. Necessary precautions must be taken to avoid short circuits due to contact with some metallic object.

14. *Cut-Outs.*—Each circuit is to be provided at its starting point with a double-pole cut-out. Each branch circuit is to be similarly fitted, and also each sub-branch carrying 5 amperes. The cut-outs must be easy of access and shielded from inflammable materials.

15. *Apparatus.*—If any piece of apparatus carries a large number of lamps, the lamps are to be divided into several groups, none of which must consume more than 5 amperes, and each group is to be provided with a double-pole cut-out. Lustres, brackets, &c., used exclusively for electricity, are to be electrically insulated at their point of support, and the body of the apparatus is not to form part of the circuit. Their sockets are to be fixed so as not to turn. When these apparatus are used both for gas and electricity they must fulfil the following conditions:—

(i.) The frame of the apparatus must be electrically insulated from the gas mains by at least 500,000 ohms.

(ii.) Incandescent lamp sockets and the framework of arc lamps must be electrically insulated from the frame of the apparatus.

(iii.) Finally the wires, well insulated and protected, are to be fixed so as to follow the shape of the apparatus, and so as not to be injured by the heat of the gas.

16. *Arc Lamps.*—Each arc light circuit is to include a switch and a fuse wire. If resistances are used they must be fixed in such a manner as to avoid contact with any inflammable material, and sufficiently removed from the wall to prevent it being injured by the heating of the wire. They must also be arranged so that circulation of the air is assured.

17. *Insulation.*—The insulation must be such that in any section of the installation the current leakage between a conductor and earth or between the two conductors shall not exceed one ten-thousandth of the current which is supplied to the apparatus connected to that section. For instance, a branch circuit traversed by 10 amperes should have an insulation such that the leakage current does not exceed 0·001 ampere, and in this particular case with 100 volts on the circuit its insulation will be at least 100,000 ohms.

* By this is meant a conductivity corresponding to a specific resistance less than 1·8 microhm-centimetre.

† [To convert amperes per square millimetre into amperes per square inch multiply by 645. Wire of ·9mm. diameter is approximately No. 20 B.W.G.—ED. *E.*]

THE RETURN TO ELECTROSTATICS.

Time's latest revenge is taking us back a century to experimental appliances of an order fondly believed by some to be as extinct as the dodo. The demand for cheap supplies of electric energy for lighting and power has led to the commercial development of systems of electrical transmission over long distances from generating stations at places where power was cheap, to centres of distribution where power would be dear, or where engines and running machinery would be inadmissible. The commercial conditions of long-distance transmission have in their turn caused a development of high potential systems, without which the cost of conductors for transmission of the current would have been prohibitive. And with the advent of high-potential systems there have come within the consideration of the electrical engineer a host of phenomena which are almost wholly absent from low-potential work. Engineers in charge of low-pressure electric generators and lamps working at only a hundred volts or so, are not much troubled with questions of static charges, or with surface leakage, or with the piercing of insulating materials by sparks. The phenomena of the Leyden jar, the charge and discharge of insulated conductors, familiar as they were to the electricians of the last century, who worked with frictional machines, and the time honoured paraphernalia of pith balls, gold-leaf electroscopes, glass-legged stools, and universal dischargers, were of no concern to the low-pressure engineer, whose stand by was Ohm's law, and whose ideal of a good insulation was expressible in megohms measured on a Wheatstone's bridge by the aid of a couple of Leclanché cells. But all this is changed with the advent of high-pressures. The surface charges that might be insignificant at a pressure of 100 volts become serious at pressures of 10,000 or even 2,000. Insulation must not

Digitized by Google

simply be regarded from the point of view of non-conduction measurable in megohms; it must be considered from the point of view of its mechanical power to resist being pierced by spark discharges. In short, electrostatics, the oldest branch of the science, which ever since the invention of the voltaic pile in the year 1800, has been dropping into second-rate importance as compared with the electrodynamic and electromagnetic branches of the science, has once more become of some significance for the industrial side of the science of electricity.

About thirty years ago there was indeed a partial revival of interest in electrostatics when a study of atmospheric electricity led Sir WILLIAM THOMSON to devise that remarkable series of electrometers, the "divided ring," the "quadrant," the "absolute," and the "portable," which still are used as instruments of research. The same great physicist has quite recently continued this series by the evolution of three new forms: the "electrostatic voltmeter," the "multicellular," and the "new gold-leaf" instruments. These are all "repulsion" instruments, mere modifications of the same fundamental principles as are to be found in the old pith-ball electroscope of JOHN CANTON, and the gold-leaf electroscope of ABRAHAM BENNET, to say nothing of the more accurate electrometer of PELTIER. Their significance lies not in their inherent principles of construction, but in the practical needs of the electric engineer which has called them forth.

Simultaneously with the evolution of the modern electrometer there has gone forward an evolution of the electrostatic generator, which if of less practical importance is of no less interest from the scientific point of view. We refer of course to the evolution of the influence machine which has superseded the old frictional machines that were previously used. "How to make a cylinder electrical machine" may be a sufficiently enthralling pastime for the amateur schoolboy to cause him to purchase a journal devoted to this sort of useless "science," but it would have been much more sensible to give him instructions how to make an influence machine of rational type. Nevertheless, the influence machine, though to-day but an instrument of research, is destined to receive more important industrial applications than to serve—as thousands of little portable influence machines to-day are serving—as a domestic gas-lighting apparatus. For thirty years also the evolution of the modern influence machine has been in progress. At that date Sir WILLIAM THOMSON and CROMWELL VARLEY were devising forms of self-exciting machines with a view to their employment in telegraphic signalling. A few years later came the further designs of TOEPLER and of HOLTZ, the latter of whom has introduced endless modifications in detail. Then came a lull, until in 1881 Mr. JAMES WIMSHURST produced the first of his now widely-known machines—the only forms of influence machine really adapted for use in an uncertain climate such as that of the British Islands.

The introduction of another branch of science into the already desperately scientific work of the electrical engineer will tend, no doubt, to create a third class. We already have continuous-current men, who set their faces against alternating intricacies; they are quite right not to bother about them if they are busy enough with what Mr. MASSEY calls the straightforward variety. We have alternating men, who, like our American cousins, want to see the wheels go round; but who leave the theory to professors and third-year students. And now, perhaps, we shall have high-pressure men, who, if not making daily use of pith balls and rubbed sealing wax, will be competent to deal with and to apply for practical purposes those thousands of volts which are the strange outcome of modern electrical engineering.

THE ELECTRICITY SUPPLY BUSINESS IN LONDON.

In devoting its energies to the thankless task imposed upon it by Parliament, the Board of Trade has naturally incurred no small amount of odium amongst electric light company promoters. However, there are compensations in all things; and it has at any rate made it possible for the unsophisticated to obtain a tolerably correct notion of the present position of the electrical supply business. In another column will be found two Tables, compiled respectively from the Capital and Revenue accounts of the eight leading metropolitan electric lighting companies, as set forth in the returns made by them to the Board of Trade for the year 1891. It has been our object in preparing these figures to enable the reader to see at a glance the main financial characteristics of each concern, and to base the Tables wholly and entirely upon the companies' accounts, as presented to the Board of Trade. With regard to the three remaining statutory electricity supply companies of the Metropolis, two, the City of London Electric Lighting Company and the New Cadogan and Belgrave Electric Supply Company, have not, at the time of writing, got properly to work; while the Electricity Supply Corporation declines to furnish us with a copy of their returns. In calculating the number of Board of Trade units sold by each Company we have merely divided the total receipts under the head of current sales by the selling price of the Board of Trade unit. Except in one case—that of the Kensington and Knightsbridge Electric Lighting Company—it has been impossible to make allowance for the rebates usually given to large customers; the total cost of production of the unit as worked out by us is, therefore, in all probability slightly too high in every case but one. We should be very glad to receive any further information as to actual output, in view of the republication of our Tables on another occasion.

Turning to the Table of Capital Expenditure we find that up to December 31, 1891, the eight companies referred to had actually spent over £2,000,000 on lands, buildings, plants, mains, &c., of which nearly £600,000, or 30 per cent., had been devoted to machinery alone. The manner in which each individual company concerned has allocated its expenditure does not exhibit so many startling differences as might have been expected. Thus the Metropolitan Company has devoted over one quarter of its money to buildings, while the average figure of its competitors may be taken at about one-sixth. On the other hand, the St. James' Company, owing to the fact that it has been obliged to locate its generating centres in the very heart of the best districts of the West-End, has expended over 21 per cent. of its capital on lands, against 0·09 per cent. for the House-to-House and 2·5 per cent. for the Metropolitan Company. Nearly half a million of money is now to be found beneath the streets of London in the shape of copper and insulation, while on meters some £27,000 has been expended.

Coming now to the Revenue Accounts, it is a matter for some thankfulness, considering the novelty of the enterprise, the severe competition, and the Parliamentary disabilities under which the electricity supply industry labours, that only two companies should have spent more than they have received. If we exclude these two unripe concerns on the one hand and the over prosperous St. James' Company on the other, the average ratio of expenditure to receipts comes out at about 75 per cent., a by no means remarkably high figure for electrical "infants." The St. James' Company, happily for its shareholders, spends but little more than sixpence for every shilling that it earns. The ratio of generating expenses to total expenditure shows some noteworthy

a This figure does *not* include the sum of £4,013 set aside for depreciation, nor the sum of £1,000 placed to "redemption fund" account.

b Proportion only.

c The selling price of the Board of Trade unit is taken from the table on pp. 144-145 of "*The Electrician*" *Electrical Trades' Directory and Handbook* for 1892. From the figures given in this Company's return it is impossible to make allowance for the usual rebates to large customers, &c, the *cost* of the unit as given is therefore, probably, slightly too high.

d During 1891 this Company sold £22,683 worth of current per meter at 7¼d. per Board of Trade unit; and £15,084 worth under contract. As the nearest approach to probability, the Board of Trade units sold under contract have been taken at 7¼d. also. That this is not far wrong can be

variations. In the case of the House-to-House Company, for instance, this ratio is nearly 80 per cent., against 32·3 per cent. for the Notting Hill Company, the average figure being approximately 60 per cent. The low-pressure and alternating companies seem much on a par in this respect. The total number of units sold during 1891 was a little over 4¼ millions, which, taking the 8-c.p. lamp at 32 watts and equivalent to a 5ft. gas burner, corresponds to 132,800,000 lamp hours, or 664,000,000 cubic feet of gas. The output of the Gas Light and Coke Company for the half-year ending December 31, 1891, was 10,000,000,000 cubic feet; so the whole of the electric lighting by supply companies corresponds at present to only 6·64 per cent. of the output of this one gas company.

Having given some rough averages, we will look more closely into some of those figures amongst which it is possible to strike an average. The amount of capital spent in land cannot be so treated on account of the wide differences, but the following averages fairly represent the proportion spent on buildings, plant, and mains:—

Average Proportion of Expenditure of Capital of the Eight Companies.

Buildings	15·5	per cent.
Plant	31·2	,,
Mains	30·6	,,
Miscellaneous	22·7	,,
	100	

When we come to the revenue accounts we find very wide differences, to be accounted for partly by different systems of allocating expenses to generation and to distribution. This difficulty is, indeed, shirked by the Westminster Electric Supply Company, which lumps these together. An example of this is found in the £163 for distribution set down by the Metropolitan Company, who supplied one and a quarter

Capital Expenditure up to December 31st, 1891, of the Statutory Electricity Supply Companies at present at work in London.

* Average of eight companies.

† Excluding London Electric Supply Company and Notting Hill Company, both of these companies running considerably below full load.

The following average costs of coal must be taken in connection with the difficulty, to which we have already alluded, of ascertaining the actual number of Board of Trade units sold. Explanations will, no doubt, be forthcoming to account for the fact that the alternating companies spend rather more than twice as much as the continuous-current companies on coal per unit.

PRICING GOODS AT THE COLUMBIAN EXPOSITION.

Last week we gave some extracts from *Engineering* upon the trick which has been tried at Chicago. It appears that the matter has turned out to be of such importance, that is to say, the participation of foreign exhibitors was recognised as being too valuable to be sacrificed, that the authorities have quickly climbed down, and the guarantees which had been cancelled are now confirmed. Our contemporary waxes indignant about this "unworthy intrigue," and says that "the unscrupulous perpetrators of the circular" have been "striking a surreptitious blow at foreign trade competitors." But the Chicago executive, which it loudly exonerates from any participation in, and even knowledge of, the stratagem, is said to be now "fully alive to the dangers to which the Exposition may be exposed from such intrigues, and they will promptly dissipate any future plots."

Some of our readers will think that this language is rather too strong. But why should the authorities be deprived of the "credit" of an example of national "smartness"?

In our article of last week we advised intending exhibitors to the Chicago Exposition not to arrive at any conclusion upon the complications that had almost suddenly arisen between foreign exhibitors and the executive of the Columbian Exposition, due to the discovery that a circular had been issued from the State Department at Washington withdrawing a privilege which had been already fully conceded to foreign exhibitors; the only important privilege that would induce industrials from abroad to be present at Chicago; and we added that the development of events could not long be delayed. We did not believe, when giving that counsel, that the solution to the difficulty was so close at hand; nor—we will frankly admit—were we prepared for so satisfactory and complete a solution in so short a time.

We have, therefore, the greater satisfaction in being able to announce on the highest official authority from Chicago, that what may be called the Wharton-Davis circular incident is at an end; that the original guarantees to foreign exhibitors which that circular annulled, are wholly confirmed; and that exhibitors may now remain quite satisfied that no further attempts will be made on the liberty of action conceded to them from the beginning on this all-important point. We have received from Chicago telegrams from the executive confirming this assurance, and we have also received from Mr. Robert S. McCormick an official communication to the same effect based on instructions sent to him from the Director-General, Colonel George Davis. As to the exact manner in which this unlooked stumbling-block that had been placed in the path of foreign exhibitors has been swept away, we are of course at present without detailed information; but we know enough of the matter to be able to say, that if on the one hand the earlier part of the incident had naturally produced a most unfavourable—we might rather say a disastrously unfavourable—impression, its conclusion throws a brilliant light upon the American method of dealing with an unjust and unworthy enterprise.

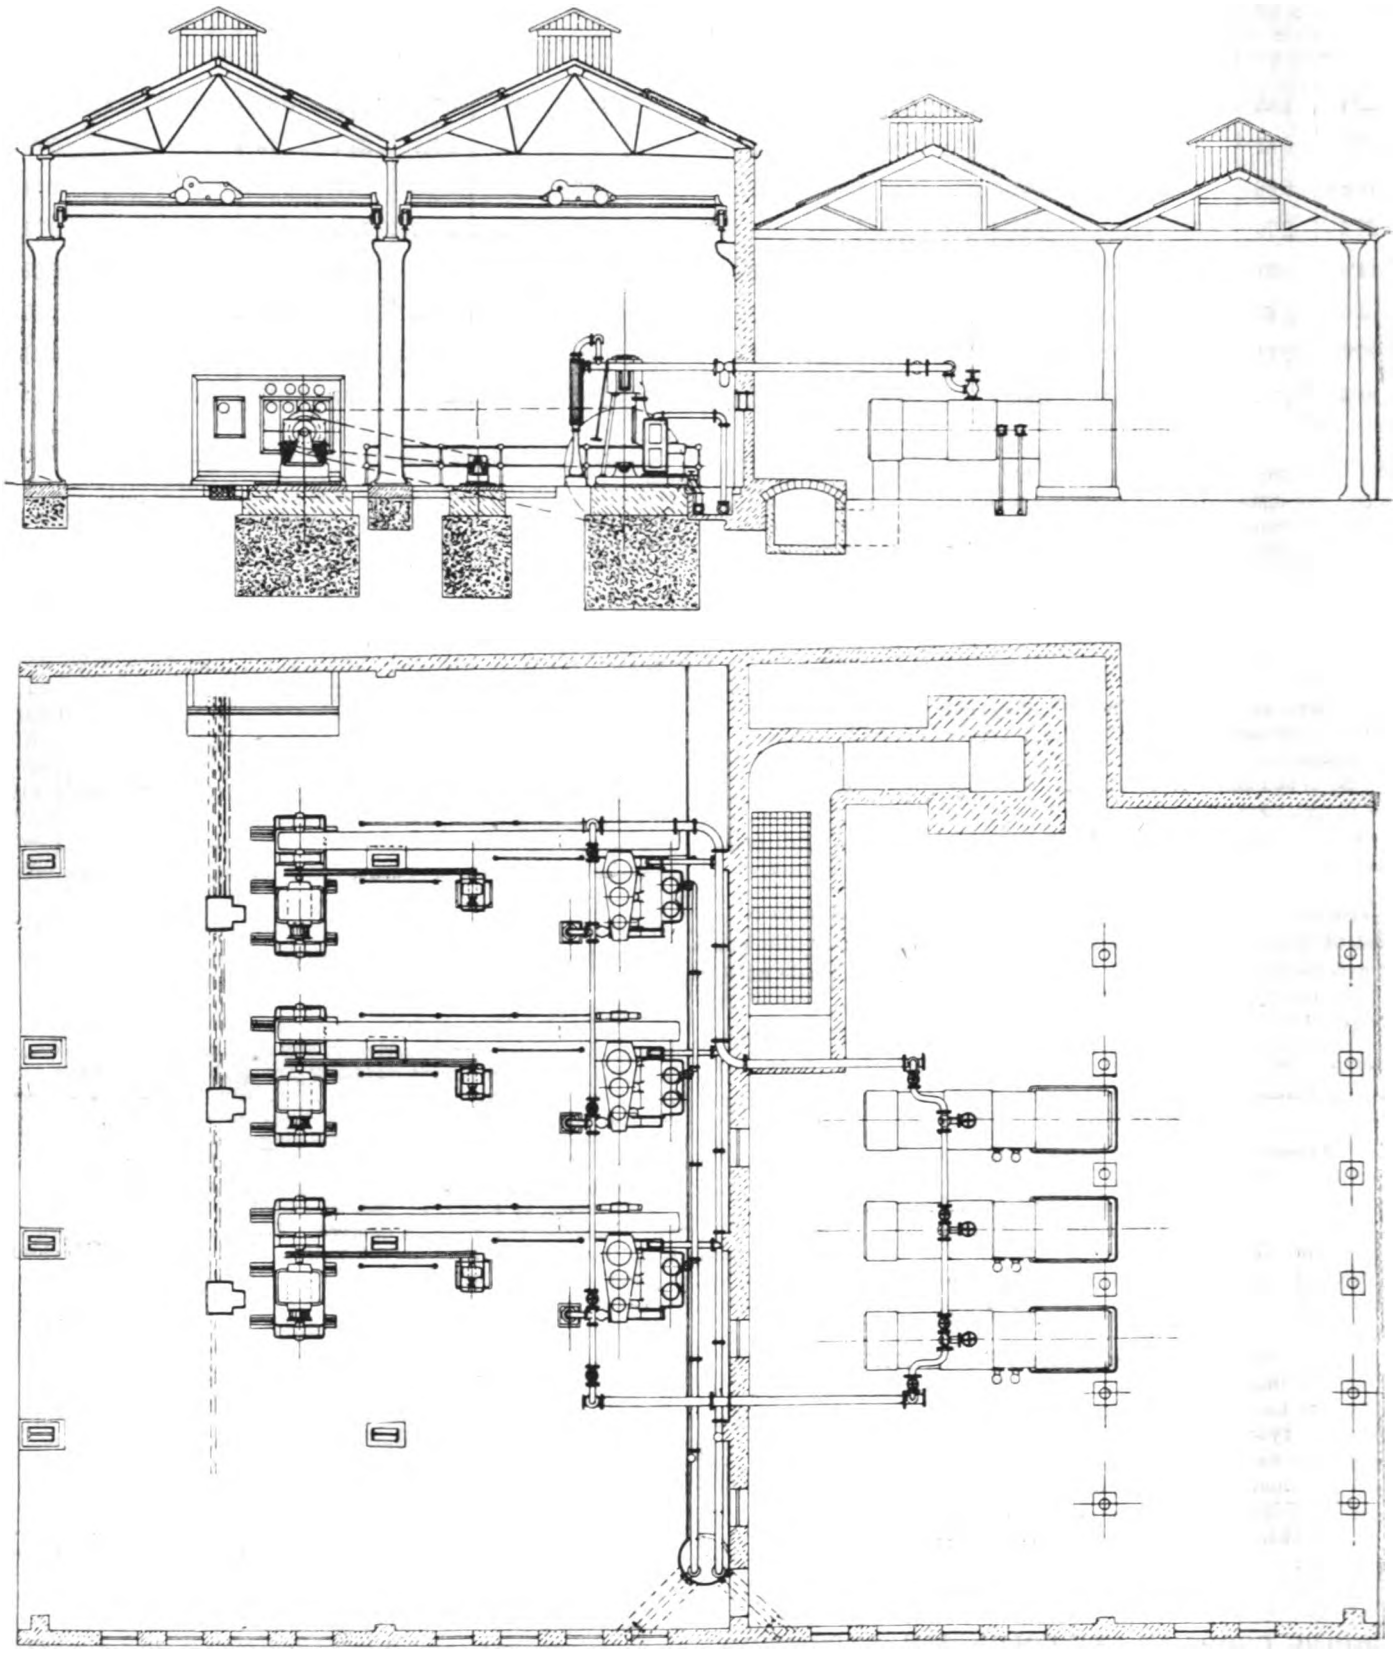
ELECTRIC SUPPLY STATION AT OXFORD.

In our issue of June 24th we gave a description of the system of electric supply used at Oxford, and this week we publish drawings of the switchboard, an illustration of the magnetic switch, and a plan and elevation of the generating station. The switchboard at the central-switch station to which we have already referred in our general description of the system (*The Electrician*, June 24, 1892, p. 195) consists of four parts or sections. The one on the left, with three ammeters, voltmeters, and resistance switches, is the battery board. The next is the termination of the high-pressure mains from the generating station. The part marked H T B is one of the "home transformer boards," and alongside this a Thomson electrostatic voltmeter is shown in outline. The part on the extreme right, consisting of four sections, is the dynamotor or continuous-current



Elevation and Plan of the Oxford Generating Station at Osney. Scale, 16ft. to 1in.

Digitized by Google

transformer board for starting and controlling the sub-station transformers. Returning to the battery board, we find surmounting the whole, three battery voltmeters, B V. Below these are the battery ammeters B A, and connected with the two outer ones are two regulating switches R S, and between them are placed two main battery switches B S. The regulating switches are coupled, as shown by the dotted lines, to different cells at one end of each battery, so that the number of cells in circuit may be altered. There are in all 114 cells, these are connected in two sets of 58 in parallel when discharging. When charging, the cells are connected in three sets of 38 in parallel, and are charged off the 100-volt network. This change in the coupling of the cells is effected by means of a throw-over and discharge switch; the switch itself is not shown in the illustration, but the terminals of it are marked C & D. At the bottom of this part of the board three regulating resistance switches R R S are fixed. The next compartment, marked G S C, contains the main ammeter and switches. The two pairs of dotted lines running downwards represent the two high-pressure mains from the generating station; and the other two, marked F E L, are future extension leads. Below these switches the battery fuses B F are fixed.

The home transformer board, of which one-half only is complete, marked H T B, is provided with the high-tension ammeter H T A, and below this is the high-tension automatic double-pole cut-out and switch H T S, very similar to the device described in *The Electrician*, Vol. XXVI., p. 108, in connection with the Manchester-square station of the Metropolitan Electric Supply Company. The starting and regulating resistance switch S R S is connected to the high-tension winding of the dynamotor, as shown diagrammatically at H T A*.

The mode of starting and regulating the dynamotors by means of this switch has been already described in our previous article. Passing now to the low-tension circuit generated in the low-tension armature L T A*, the mains pass upwards to the automatic cut-out A C, and thence, through the low-tension switch L T S, to the low-tension supply network. The current being indicated on the ammeter N A, and the pressure on the voltmeter N V. It is intended, when the demand increases, to provide another dynamotor at the central-switch station; and the necessary switches will be provided on the space shown vacant. The four sets of switches shown on the right, control the distant dynamotors. A dynamotor and magnetic switch are shown diagrammatically, connected with the low-tension network L T N. Pilot voltmeters, P V, at the top of this board show the pressure at various points on the network. When the pressure at any point is found to be falling, and the attendant judges that the assistance of a dynamotor is necessary, he closes the low-tension operating switch L T O, which short-circuits the voltmeter P V, and allows a current to flow through the long-pull magnet of the magnetic switch. We give two outline illustrations and a reproduction of a photograph of this ingenious device. The iron core and armature disc are clearly shown in Figs. 2, 3, and 4, below the iron-clad solenoid. The pilot-voltmeter circuit passes round these solenoids, but the feeble-voltmeter current is of course unable to move the armature. On closing the switch L T O, Fig. 1, the armature is lifted, and raises the links and pawls which hang from it. This action pushes round the ratchet wheel, and the opening of the switch immediately afterwards allows the links and pawls to drop, moving the ratchet wheel again. This causes the double-break switch to open or close alternately as has been already described. A massive coil of three turns carrying the whole low-pressure current, if strongly excited by a heavy load or short circuit, raises the hinged armature and allows a strong spiral spring to pull open the switch.

motor A was run from a generator giving 100 volts. The current was transformed by it to 1,050 volts, and this was used to drive a second dynamotor B, transforming down again to

Digitized by Google

100 volts. The same instruments were used for both sets of readings, being transferred from circuit A to circuit B, thus practically eliminating any error due to the instruments. The actual readings are shown in Fig. 6, as circles on the full line, this gives the combined efficiency of the two dynamotors. The dotted curve gives the efficiency of a single one for different outputs. We learn that the lighting is giving every satisfaction, and that two colleges are about to begin wiring immediately.

THE VARLEY FUND.

On Friday last week a meeting was held in the Westminster Palace Hotel to consider some means of recognising the services rendered to the electrical industry by the discoveries of Mr. Samuel Varley. Lord Kelvin presided, and was supported by Profs. Silvanus Thompson, J. Perry, D. E. Hughes, Major Flood Page, Messrs. R. E. B. Crompton, Alex. Siemens, &c. Lord KELVIN, after a few preliminary remarks, called upon Mr. Crompton to open the proceedings.

Mr. CROMPTON briefly alluded to the circular which had been sent out calling the meeting, and said he had received a number of replies from Sir Frederick Bramwell, Sir Henry Mance, Prof. Kennedy, Dr. Oliver Lodge, Mr. Preece, and others, all of them speaking very highly of Mr. Varley's work, and wishing to be added to the Committee.

Mr. GATEHOUSE then read a Paper giving a brief sketch of Mr. Varley's life and work, and concluded by pointing out that Mr. Varley's labours had been animated by the true spirit of science, and that in his inventions he had sought the good of the greatest number rather than to reap pecuniary advantage for himself.

Mr. CROMPTON was ashamed to say that until the compound-winding trial, he had known but very little of Mr. Varley's labours. He had been working at the same subject for a long time, but without knowing how thoroughly Varley had already covered the ground, and how completely he had grasped the principles of the subject. As some of them knew, Mr. Varley had not worked for his own advantage, and had not succeeded so well in business as they could wish; and he thought, therefore, that engineers, who had derived so much benefit from his works, ought to take this opportunity of recognising in some substantial way the debt they owed to Mr. Varley. He thought that they might, perhaps, in conjunction with the Institution of Electrical Engineers, approach the Government and obtain a pension from them, which might be supplemented, if necessary, by subscription.

A short discussion then ensued as to the details of the statement to be circulated, in which Profs. Perry, Silvanus Thompson, and Mr. Siemens took part. Mr. Siemens called attention to a letter, which appeared in the *Engineer*, pointing out that Sir Charles Wheatstone first invented compound winding, Mr. Varley first patented it, and Werner Siemens was the first to publish it. It was agreed that the meeting could not commit itself to Mr. Gatehouse's Paper as it stood.

Lord KELVIN suggested that the statement might be supplemented by the addition of the above facts, and pointed out that the law courts only dealt with facts as to the actual patent, irrespective of the date of invention. There seemed no doubt that all three discovered compound winding independently, and almost simultaneously. Among other matters it was suggested that a statement setting forth what Mr. Varley has done should be prepared by Messrs. Siemens, Gatehouse, Silvanus Thompson and Crompton, and this statement should be circulated as widely as possible among members of the electrical profession at home and abroad.

The following resolution was put and carried:—"That this meeting approves of a testimonial being got up on behalf of Mr. S. Varley, and that the whole of these gentlemen who have given their names as willing to serve on the Committee be and are hereby appointed a Committee to act in the question of the Varley testimonial; and that an Executive Committee be hereby appointed, consisting of Lord Kelvin, Prof. S. Thompson, Prof. Perry, Mr. A. Siemens, and the gentlemen who attended the preliminary meeting."

London Chamber of Commerce.—A meeting of the Electrical Trades Section will be held at the offices to-day (Friday), at 3·30 p.m., when the following agenda will be considered:—(1) Minutes. (2) Report of Special Committee appointed to consider the County Council Bye-laws on Overhead Wires. (3) Report as to the action taken by the Special Electrical Traction Committee. (4) Report of the Special Chicago Exhibition Committee. (5) Standardising of machinery. (6) Uniformity of prices. (7) Foreign competition.

CRYSTAL PALACE ELECTRICAL EXHIBITION, 1892.

LIST OF JURORS.

Prof. W. Grylls Adams, D.Sc., F.R.S.
Mr. L. Atkinson, A.M.Inst.C.E.
Prof. W. E. Ayrton, F.R.S.
Mr. Shelford Bidwell, M.A., F.R.S.
Mr. Conrad W. Cooke, M.Inst.E.E.
Prof. W. Crookes, F.R.S.
Mr. W. B. Esson, M.Inst.E.E.
Prof. Geo. Forbes, M.A., F.R.S.
Major-General Festing, R.E., F.R.S.
Capt. Sir Douglas Galton, F.R.S.
Dr. J. H. Gladstone, F.R.S.
Mr. J. H. Greathead, M.Inst.C.E.
Mr. Charles Hall, M.Inst.E.E.
Prof. D. E. Hughes, F.R.S.
Sir Henry C. Mance, C.I.E.
Mr. W. H. Massey, M.Inst.C.E.
Prof. J. Perry, F.R.S.
Mr. W. H. Preece, F.R.S.
Mr. A. Reckenzaun, M.Inst.E.E.
Prof. Henry Robinson, M.Inst.C.E.
Capt. Sankey, R.E., M.Inst.E.E.
Mr. C. E. Spagnoletti, M.Inst.C.E.
Mr. Albion T. Snell, M.Inst.E.E.
Mr. W. E. Sumpner, D.Sc.
Mr. Jas. Swinburne, M.Inst.E.E.
Prof. Silvanus Thompson, F.R.S.
Mr. J. Tomlinson, M.Inst.C.E
Prof. W. C. Unwin, B.Sc., M.Inst.C.E.
Major-General Webber, C.B., R.E.
Mr. J. W. Wilson, M.Inst.C.E.

The following are the awards made by the jurors:

Diploma of Honour.

H.M. Post Office.
L. B. and S. C. Railway Company.
L. C. and D. Railway Company.
L. and N.-W. Railway Company.
National Telephone Company.
Exchange Telegraph Company.
Crossley Bros.
Swinburne, J., and Co.
Willans and Robinson.

Diploma of Honour and Gold Medal.
(Highest Award.)

Brush Electrical Engineering Co.
Crompton and Co.
Johnson and Phillips.
Edison and Swan United Electric Light Company.
Siemens Bros. and Co.

Gold Medal.

Coxeter and Son.
Davey, Paxman, and Co.
Easton and Anderson.
Electric Construction Corporation.
Electrical Power Storage Company.
Glover, W. T., and Co.
Henley's, W. T., Telegraph Works Company.
Laing, Wharton, and Down Construction Syndicate.
Nalder Bros. and Co.
Saxby and Farmer.
White, J.

Silver Medal.

Acme Electric Company.
Anderson, R., and Co.
Andrew, J. E. H., and Co.
Andrews, J. D. F., and Co.
Armstrong's Glass Co.
Barclay and Son.
Benham and Froud.
Bristöl, L.
Britannia Rubber and Kamptulicon Company.
British Gas Engine Company.
British Stone and Marble Company.
Browett, Lindley and Co.
Campbell Gas Engine Co.
Chubb and Son.
Consolidated Telephone Company.
Davis and Timmins.
Day and Co. (Bath).
Dent and Co.
Dick, Kerr, and Co.
Edison Manufacturing Company.
Epstein Accumulator Company.
Ferranti, S. Z. de.
Fielding and Platt.
Fowler-Waring Cables Company.
General Electric Company.
Giles, F., and Co.
Groves, W.
Groth, L. A.
Gülcher (New) Electric Light and Power Company.
Hammer, W. J.
Joel, H. F., and Co.
Laing, Wharton, and Down.
Lloyd and Lloyd.
London Metallurgical Company.
Mosses and Mitchell.
Osler and Co.
Rashleigh Phipps and Dawson.
Richard Frères.
Richards, F. M.
Scott, Ronald A.
Shirley and Co.
Trent Gas Engine Company.
Warby, J. L.
Waygood and Co.
Wells Bros.
Western Electric Company.
Weymersch Battery Syndicate.
Woodhouse and Rawson United.

Bronze Medal.

Allsop and Co.
Anders, Elliot, and Chetham-Strode.
Appleton, Burbey, and Williamson.
Archer Pipe Company.
Becker and Co.
Bishop, W. J.
Bowron, G.
Burnby and Son.
Capitaine Gas Engine Company.
Charlesworth, Hall and Co.
Cooper, H. and J.
Croggon and Co.
Dorman and Smith.
Electric Stores.
Faraday and Son.
Fowler, Lancaster and Co.
Habgood, W. J.
Hartnell, Wilson.
Hindley, E. S.
Hookham, Townley and Co.
Homacoustic Speaking Tube Company.
International Electric Company.
Jenner, T.
Jennings, G.
Jones, A.
Lacombe and Co.
Lewis, J.
Lundberg, A. P.
Maquay Electric Light Syndicate.
Mayer, H.
Mining and General Electric Lamp Company.
Napier and Son.
Newton, F. M.
Riedel, J.
Roberts, Adlard and Co.
Roper's Electrical Engineering Co.
Smith, Samuel, and Son.
Spencer, Edward, and Co.
Spencer, J.
Stegmann, G.
Taylor and Tucker.
Telegraph Manufacturing Co.
Thorpe, Harry.
Tipping, H. S.
"Trusty" Engine.
Zeitz and Co.

PHYSICAL SOCIETY.

At the ordinary meeting of this Society, held on June 24th, Prof. A. W. Rücker, F.R.S., in the chair, a Paper was read by Mr. W. B. Croft on

"Breath Figures."

He described a number of interesting experiments by which latent impressions of objects such as coins could be made upon glass plates. When such objects were electrified the figures were developed by breathing upon the glass. Prof. Silvanus Thompson referred to other curious latent impressions of a mechanical description upon glass and porcelain.

A Paper was read by Mr. E. Wythe Smith

"On the Measurement of the Internal Resistance of Cells,"

In order to determine the actions which take place in an accumulator during charge and discharge, it is necessary to know the working E.M.F. at the different stages. This might be observed by breaking the circuit; but immediately on doing this the E.M.F. varies at a very rapid rate, so that if only four or five seconds be occupied in taking the measurement an error of 25 per cent. may be made in the difference between the E.M.F. and the terminal potential difference. If time-readings be taken after breaking the circuit and a curve drawn connecting E.M.F. and time, this curve may be produced back in the way described by Prof. Ayrton and others in a Paper at the Institute of Electrical Engineers. But as this method has its objections, in addition to that of interrupting the circuit, it is very desirable to determine the actual working E.M.F. in some other way.

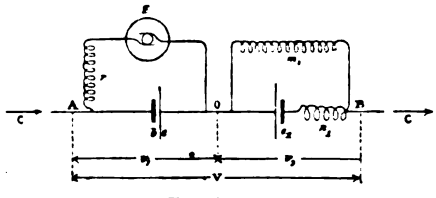

Fig. 1.

The E.M.F. could be readily obtained from the terminal potential difference and the current if the internal resistance were known. It is for the determination of this latter quantity that I have devised the following modification of Mance's method. Of course this method is applicable to the measurement of the resistance of other forms of battery besides accumulators.

In Fig. 1 let the cell of E.M.F. e, and internal resistance, b, be the one experimented upon, r being the resistance of the external circuit which contains an E.M.F., E, for example, that of the dynamo used to charge the cell. This circuit is connected at O with an auxiliary circuit, in which the resistances m_1 and n_1 are so adjusted that the points A and B are at the same potential, the resistance of the cell of E.M.F., e_1, being included in n_1. Suppose a current, C, from some external source to pass through both circuits in series. The potential difference between A and B will now be V. Let potential difference between A and O be v_1, and that between O and B be v_2, $(v_1+v_2)=V$. We have

$$C=\frac{v_1+e}{b}+\frac{v_1+E}{r}=\frac{v_2-e_1}{n_1}+\frac{v_2}{m_1};$$

therefore
$$v_1=\frac{b\,r\,C-r\,e-b\,E}{b+r},$$

and
$$v_2=\frac{m_1\,n_1\,C+m_1\,e_1}{m_1+n_1}$$

$$V=\frac{b+C-r\,e-b\,E}{b+r}+\frac{m_1\,n_1\,C+m_1\,e_1}{m_1+n_1}.$$

But when C=O, V=O,

$$\therefore\ O=\frac{-r\,e-b\,E}{b+r}+\frac{m_1\,e_1}{m_1+n_1};$$

$$\therefore\ V=C\left(\frac{b\,r}{b+r}+\frac{m_1\,n_1}{m_1+n_1}\right).$$

If we measure the apparent distance R_1 between A and B by any convenient method, and if C be the current sent through this circuit between A and B by the testing arrangement, we get R_1 equal to $\frac{V}{C}$;

$$\therefore\ R_1=\frac{b\,r}{b+r}+\frac{m_1\,n_1}{m_1+n_1}.$$

Now if we have three circuits (Fig. 2) connected together at the point O, the cell of E.M.F. equal to e and resistance b being the particular one whose resistance is required, and if the resistances m_1, m_2, n_1, n_2 be so adjusted that the points A, B, and C are at the same potential, the apparent resistances R_1, R_2, R_3 between the points A and B, A and C, and B and C, will have the following values:—

$$R_1=\frac{b\,r}{b+r}+\frac{m_1\,n_1}{m_1+n_1},$$

$$R_2=\frac{b\,r}{b+r}+\frac{m_2\,n_2}{m_2+n_2},$$

$$R_3=\frac{m_1\,n_1}{m_1+n_1}+\frac{m_2\,n_2}{m_2+n_2};$$

$$\therefore\ \frac{b\,r}{b+r}=\frac{R_1+R_2-R_3}{2},\ \text{say, equals } x,$$

then the required resistance of the cell,

$$b=x+\frac{x^2}{r}+\frac{x^3}{r^2}+\&c.$$

If, as in the case of an accumulator, x is small compared with r, then

$$b=x+\frac{x^2}{r}.$$

When an accumulator is discharging, taking $b=x$ gives us a value for b about 2 per cent. too low.

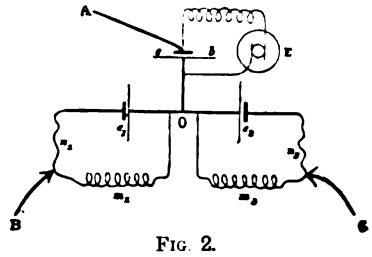

Fig. 2.

If a Wheatstone bridge be employed to measure R_1, R_2, and R_3, there will be no necessity to employ any special instrument in the testing for equality of potential of the points A, B, and C. For all that need be done is to remove an infinity plug on the bridge, close the galvanometer circuit, but not that of the testing battery, and adjust m_1, m_2, n_1, n_2 until the galvanometer remains at zero.

DISCUSSION.

Prof. PERRY inquired how far the results obtained agreed with those got by the older methods, and whether they depended on the time the keys were kept down. In the old methods it was assumed that an instantaneous rise in potential difference occurred on breaking the circuit. This might or might not be true. He was inclined to regard the potential difference and current as functions both of resistance and time. The behaviour of cells seemed to indicate the existence of something like capacity, or rather capacities and resistances in series.

Prof. AYRTON said the Paper was of great interest, for it made possible what could not be done before, viz., to find the resistance of a cell without appreciably altering the current through it. Although the new method required more cells this was not prohibitive, for the result sought was of considerable scientific importance. The same method was applicable for finding the resistance of dynamo armatures when working a quantity which had hitherto been unattainable by direct measurement.

Mr. LANE FOX said the perplexing changes in the potential difference of secondary cells were to be accounted for by changes in the electrolyte which occurred in the pores of the plates. He could detect no flaw in the reasoning given in the Paper.

Dr. SUMPNER remarked that the method was a valuable one, for it depended on bridge tests which could be made with considerable accuracy. On the other hand, it was a false zero method, and therefore liable to errors arising from changes of this zero.

Prof. AYRTON pointed out that these errors could be eliminated by reversing the bridge battery.

Mr. RIMINGTON said, although the testing currents were small, they might affect the E.M.F., and thus introduce an error in b. This might be tested by using alternate currents and a telephone.

In reply to Prof. Perry, Mr. SMITH said the results agreed with those obtained by the older methods to within the limits of accuracy obtainable by the latter methods; this might amount to something like 15 per cent.

A Paper was read

"On the Relation of the Dimensions of Physical Quantities to Directions in Space,"

by Mr. W. Williams.

In February, 1889, Prof. Rücker recalled attention to the fact that in the ordinary dimensional formulæ for electrical quantities the dimensions of μ (permeability) and k (specific inductive capacity) are suppressed. In the discussion on that Paper Prof.

Digitized by Google

S. P. Thompson pointed out that lengths should be considered as having direction as well as magnitude; for, if so regarded, difficulties arising from different units, such as *couple* and *work*, having the same dimensions would be avoided. Developing this idea, the author takes three mutually perpendicular lines along which lengths are measured. Calling unit lengths along these lines X, Y and Z respectively, the various dynamical units, such as velocity, acceleration, force, work, &c., are expressed in terms of M, T, X, Y, and Z. The formulæ, then, denote the directional as well as the numerical relations between the units; and the dimensional formulæ are therefore regarded as the symbolical instead of by powers of a single length, and angles and angular displacements by quotients of rectangular vectors, instead of being expressions of the physical nature of the quantities, so far as they depend on length, mass and time. In this system areas and volumes are represented by products of different vector lengths, pure numbers. For physical purposes pure numbers may be defined as ratios of concretes of the same kind similarly directed (if directed at all). A plane angle has dimensions $X^{-1}Y$, X being in the direction of the radius, and Y that of the arc, whilst solid angles have dimensions YZX^{-2}, and radii of curvature Y^2X^{-1}. It is also shown that π is a concrete quantity of the dimensions either of plane or of solid angle. This is of considerable importance in connection with the radial and circuital fluxes in the electro-magnetic field.

In deducing the dimensional formulæ for electrical and magnetic units, the rational and simplified relations given by Mr. Oliver Heaviside in *The Electrician*, of October 16th and 30th, 1891, are used. Instantaneous axes are taken at any point of an isotropic medium (the ether), such that X coincides with the electrical displacement, Y with that of the magnetic displacement, and Z with the intersection of the two equi-potential surfaces at that point. Starting with the relation μH = energy per unit volume, the formulæ for the various quantities in terms of μ are obtained. These simplify down to those of the ordinary electro-magnetic system, by putting $\mu = 1$ and suppressing the distinction between X Y and Z. Similarly, commencing with kE^2 = energy per unit volume, formulæ in terms of k are obtained, which, when simplified as above, give those of the ordinary electrostatic system. Examples of the consistent way in which the results work out are given in the Paper, and the whole subject is discussed in detail both by cartesian and vectorial methods.

The formulæ in terms of μ and k are used to trace out and examine the various analogies between electro-magnetism and dynamics, thereby obtaining a connected dynamical theory of electro-magnetism. Inquiry is then made as to what dimensions of μ and k in terms of M, T, X, Y, Z render the interpretation of electrical and magnetic units simple, natural, and intelligible as a whole. The conditions imposed (for reasons stated in the Paper) are—1st, that the dimensions of μ and k satisfy the relation $[\mu k] = Z^2T^{-2}$; 2nd, that the powers of fundamental units in the dimensional formulæ shall not be higher or lower than those found in the formulæ of the ordinary dynamical quantities; and 3rd, that quantities which are scalar or directed must also be scalar or directed when these dimensions are expressed absolutely. Subject to these conditions, it is shown that the possible dimensional values of μ and k are eight in number. Of these only two lead to intelligible results. These are—I., $\mu = M(XYZ)^{-1}$, and $k = M^{-1}XYZ^{-1}T^2$; and II., $\mu = M^{-1}XYZ^{-1}T^2$, and $k = M(XYZ)^{-1}$. According to I., μ is the density of the medium, electrical energy is potential, and magnetic energy kinetic. By II., k is the density of the medium, electrical energy is kinetic, and magnetic energy potential. Full interpretations of the dimensional formulæ of all the electro-magnetic quantities, as obtained in accordance with the above conditions, are given in the Paper.

DISCUSSION.

Prof. S. P. THOMPSON said the Paper was a very important one, and thought the idea of finding dimensions for μ and k, which would rationalise the ordinary dimensional formulæ, a great step. The use of vectors was a valuable feature, whilst the employment of X, Y, and Z instead of L, removed many difficulties connected with dimensional formulæ. Other difficulties might be cleared up by paying attention to the signs of the vector products and quotients, and to the order in which the symbols were written. Another important matter was the use of Mr. Heaviside's "rational units," a system which merited serious attention. In conclusion, Prof. Thompson expressed a hope that, in accordance with a resolution of the Electrical Congress at Frankfort, both permeability and specific inductive capacity should be designated by Greek symbols.

Prof. O. HENRICI expressed his admiration of the way in which the subject had been treated in the Paper. He had long held that clear ideas of physical quantities were best got by vectorial methods. He also congratulated the author on his treatment of plane and solid angles as concrete quantities.

In a communication addressed to the Secretary, Prof. O. J. LODGE remarked that physicists in England were more or less familiar with the advantages of retaining μ and k in dimensional expressions before Prof. Rücker's Paper of February, 1889, brought the matter closely home to students. The system of mechanical dimensions suggested for electrical quantities in an appendix to "Modern Views of Electricity," was not put forth as the only one possible, but as one having certain probabilities of truth in its favour.

Prof. RÜCKER said that although Mr. Williams and himself had talked over certain minor points in the Paper, the main ideas brought forward were quite original, having been fully developed by Mr. Williams before the author mentioned the subject to him (Prof. Rücker).

A Paper on "Molecular Forces," by Mr. W. SUTHERLAND, communicated by Prof. CAREY FOSTER, was taken as read.

The CHAIRMAN announced that both this Paper and that of Mr. Williams would be printed in the *Philosophical Magazine* during the long vacation, so that they could be fully discussed early next session.

LEGAL INTELLIGENCE.

Lane Fox v. Kensington and Knightsbridge Electric Lighting Company (Limited).

COURT OF APPEAL.—WEDNESDAY, JUNE 29TH.

Mr. R. WALLACE, who was placed at some disadvantage by the loss of his notes of the case, together with memoranda and index of the evidence, in resuming his address to the Court, dealt with Prof. Ayrton's curves of charge and discharge of accumulators, and read extracts from Mr. Drake's evidence. Lord Justice Kay said that he understood that when the battery was charged the volts rose quickly to the point D (see *The Electrician*, Vol. XXVI., p. 102), and that then it bubbled. Mr. Wallace said that was so, and that on beginning to discharge there was a drop of 25 volts. It had been assumed, he said, that the "plateau" of charge was identical with the "plateau" of discharge, but that it was not fair to consider them as being on the same level. They were shown on opposite sides of the page in Ayrton's Paper, and that was how the idea of the "plateau" got into the mind of Mr. Lane Fox's witnesses and of the Attorney-General. The "plateaux" were not at the same level, and therefore it was evident that the "plateau" theory must vanish.

Various curves of experiments were put in, and one of their Lordships asked, "What does B.D. mean?" "Benjamin (!) Drake," was the reply "Then what does P.D. mean?" "P.D. stands for potential difference." After further reading of evidence on charging and discharging of storage batteries Mr. Lane Fox rose and said that he did not dispute that at all; it was all irrelevant, this charging at high volts was not necessary, except for commercial reasons of storage. Lord Justice Kay asked whether it was necessary to charge up as far as B. A long series of extracts from the evidence was then read, and Mr. Lane Fox again rose to say that he did not dispute it. Mr. Wallace said that it was suggested that if they went to a less degree of charge, less current would go in, and they would have to do it for a long time, and it could not be done under a long time. Lord Justice Kay: "Is it necessary to go to B?" Mr. Wallace: "Unless you do you cannot charge at all." Lord Justice Kay: "But fully charge? Lane Fox says you need not got so far." Mr. Wallace: "If you do, you do not get on to the plateau——" Lord Justice Kay: "But we want the evidence." Mr. Wallace: "That is shown——" Lord Justice Kay: "The evidence! the evidence!" Mr. Wallace then read from Prof. Kennedy's evidence.

After a considerable number of extracts from the evidence had been read, Lord Justice Kay said that all that was for the sake of the batteries.

Evidence on an attempt to charge a battery at a pressure never more than 1 per cent. above the normal was then read; and Mr. Wallace said that it would not suffice to supply any practical demand in ampere hours. Lord Justice Kay asked for an explanation of the term ampere-hour, and Mr. Wallace attempted at first to illustrate it by reference to an income of £500 a year, and afterwards by a quantity of water flowing in a stream of so many gallons a minute. After some discussion the Judges failed to understand the explanation, and called on Mr. Lane Fox for assistance. He stated that an ampere hour was a measure of capacity, and represented an ampere flowing for an hour, and that was so much energy. Lord Justice Lopes said that some clear explanation of the term would probably be found in an excellent book by Miss Marie Caillard on Electricity. When at length some idea of an ampere hour had been arrived at, Lord Justice Kay said, "All this is for a great store of current, but Lane Fox does not want it." Mr. Wallace then read extracts from Mr. King's evidence on the point of utility. Extracts from the evidence of Messrs. Miller and Swinburne were then read, and in reply to one of the Judges Mr. Wallace said that the batteries might stop the flicker, but that was not the regulation which Mr. Lane Fox had intended.

Evidence on the use of the switches was then read, and Lord Justice Kay said that they appeared to be an improvement, and it did not show that the system would not work at all without switches. Further evidence was read, but his lordship said that it would only be material if it could be shown that the system would not work without switches. The evidence of Prof. S. P. Thompson was read. Lord Justice Kay remarked that the switches were an improvement for regulation. The evidence of Mr. Crompton was then quoted to show that the system would not work without switches, and a long extract from Mr. Millar's evidence was read.

THURSDAY, JUNE 30TH.

Mr. Lane Fox having omitted to refer to many parts of the evidence during his opening address, Mr. WALLACE read many extracts at Mr. Lane Fox's suggestion; and after the mid-day adjournment Lord Justice Lindley announced that the Court had decided to read the whole of the evidence, but wished to know which portions were considered important. Further extracts from Mr. Drake's evidence were read by Mr. Wallace. A

Digitized by Google

discussion between the Judges and Counsel arose on the short duration of the regulation which was admitted by the witness, and on the aims of Lane Fox and of the defendants in their use of secondary batteries. After the reading of the evidence of Prof. S. P. Thompson and Prof. Barrett, Mr. Wallace said that it amounted to this: that the batteries were of no value for regulating. When they were fully charged they were just enough to prevent a flicker. Lord Justice Kay said that he could not understand the evidence of Mr. King. In one place he said that the batteries when charged would prevent flickering for a few moments only; and in another place he said that you may shut up the place, and the batteries would run the lamps all night. Lord Justice Lopes said that he could not understand this contradiction, and Lord Justice Kay repeated that he was unable to reconcile the evidence of this witness on pages 639 and 641 of the shorthand notes.

Passing to the question of switches, further evidence was read, and Lord Justice Kay said that if the invention of Lane Fox was such that it would regulate for a short time, their addition of switches would not affect Lane Fox. The evidence on Prof. Kennedy's tests of batteries was then read; and Mr. Lane Fox, interposing, said that in this case the batteries were not connected to the mains, and it could not be compared with actual work. After copious extracts from evidence, Lord Justice Kay asked why the lamps could not be run from the mains, when both they and the batteries had dropped to 50 volts? Mr. Wallace explained that 100-volt lamps would give no light at 50 volts. Lord Justice Kay referred to other parts of the evidence to show that at 50 volts lamps worked satisfactorily. Lord Justice Lopes thought that that would be an excellent way of working, and that the regulation would then be perfect. Mr. Wallace explained that there was a difference between 100-volt lamps and 50-volt lamps in the thickness and resistance of their filament.

Extracts from Mr. King's evidence were read, in which experiments made for the purpose of the trial were described. A constant current of 80 amperes was used, and the resistance of the circuit being varied, there was a corresponding change in the volts. Diagrams of curves were shown; but after a long explanation Lord Justice Kay said that he did not understand a single word of it. Mr. Lane Fox rose to ask if he had a right to reply on this evidence. Lord Justice Lindley said, "Of course;" and Mr. Lane Fox remarked, "It is all absolute nonsense." After further evidence on the behaviour of batteries, Lord Justice Kay said, "If that is not regulation, I should like to know what regulation is." Mr. Wallace said that that kind of regulation was not what the defendants used batteries for. He denied the utility of it, and said that a battery would only be wasted if it were used for that, and that it would be better to use a dynamo instead. After extracts from Dr. J. Hopkinson's evidence, Lord Justice Lindley said that there was a difference between utility now, and utility in 1878; the Lane Fox system might not be useful now, but it might have been in 1878. Mr. Wallace said that there had been no invention; if Lane Fox had invented a battery it would have been a different thing.

Prof. Perry's evidence about the use of the Lane Fox system at the Grand Hotel, Charing Cross, was read, and Mr. Wallace said that he had had to use switches. Lord Justice Kay said, "No, 'he did use switches,' not 'he had to.'" Evidence about the exhibits at the Crystal Palace and at Paris and Lady Conyers's ball was read; and the switches were described as an obvious development. Mr. Wallace said that Mr. Lane Fox merely took a Planté battery which everybody knew about, and used it to do work which everybody knew it would do, showing no novelty or invention. Anybody might have done it. Lord Justice Kay said, "The man who first applied secondary batteries to dynamos and lamps was a great inventor." Soon after this the Court adjourned.

FRIDAY, JULY 1ST.

Evidence of early examples of incandescent lighting at the Palace of the King of Roumania and elsewhere was read by Mr. WALLACE, and attention was called by him to the fact that switches were used. He read the passage in which Lane Fox claimed to have invented these switches, that Prof. Perry had invented eight years after, and that Mr. Crompton had invented them a few years ago. Mr. Lane Fox rose to say that this was said in joke. The work at the Vienna Opera House and at the Law Courts was referred to, and parts of the cross-examination of Mr. Lane Fox were read. After the first week, the lamps at the Law Courts flared up when the batteries were being charged, but were only red hot when they were run direct from the batteries. Extracts from Mr. Crompton's evidence were read, showing that Faure-Sellon-Volkman cells were used, that the lamps were run from compound dynamos, and that before accumulators were used the light was very good. Lord Justice Kay said, "But they charged the battery to a high point"; Lane Fox says he does not, and that if you do so you must use switches. Mr. Wallace admitted that that was so. Lord Justice Kay continued that if the batteries were charged with 125 volts, switches must be used and the whole question was whether it *was* necessary. Lane Fox, he added, said no. The model (*The Electrician*, Vol. XXVIII., p. 158) was handed up to their lordships, and Mr. Wallace read the description of several of the positions; while Mr. Goddard, solicitor for the defendants, adjusted the wheels, slides and switches. Lord Justice Kay said that it seemed to be a mode of showing that if they had high volts they must have some way of preventing the high-pressure getting to the lamps.

The patent specification, which up to this point in the appeal had received hardly any attention, was read and commented upon by Mr. Wallace. Lord Justice Kay asked whether any word in the title referred to the battery except the word "regulation." Mr. Wallace replied that as the title stood regulation did not refer to the battery, but that "distribution" referred to it. Lord Justice Kay: "But that is left in." Lord Justice Lindley: "The point is that the mode of regulation is altered." Mr. Wallace said that one of the objects of the system was to overcome the resistance of the mains.

Arguing on the insufficiency of the specification, Mr. Wallace said that Lane Fox had not described a workable invention, and the description was ambiguous. He read the following passage from the specification:—The electromotive force of the electric conducting mains should be kept as nearly as possible constant at, say, 100 volts or British Association units of electromotive force. The emphasis, he said, was not on "constant"; that was not important, but on "100 volts." Lord Justice Lindley pointed out that Lane Fox had put it "say, 100 volts." He seemed to have made a good shot. Mr. Wallace said that 100 was a round number. Lord Justice Kay said that "100 volts" could not be the pith of the sentence, because it was preceded by the word "say." It was obvious that the pith was in the word "constant." Mr. Wallace said that while lamps could be made for 50 volts, or lower pressures, Mr. Lane Fox's object was to use high resistance, so as to get over the resistance of the mains. Lord Justice Kay said that that did not impress his mind; and Lord Justice Lindley concurred. Passing to the reference to the batteries, Lord Justice Kay said that the words were "such as Planté," which was very like the other expression, "say." Another passage from the specification was read, and one of the Judges asked what was the object of a reservoir if not to keep the volts constant. Mr. Wallace said it was distinctly claimed *not* that the pressure should be constant, but "to increase the electromotive force." Lord Justice Kay said, "But if the mains drop, *then* it would increase it." Lord Justice Lopes said that the mains would be recouped when the pressure had fallen. Lord Justice Kay observed that they were not talking of current, but of electromotive force. Lord Justice Lindley asked Mr. Wallace how he read the passage; and he replied that Mr. Lane Fox wanted to dot batteries about over a large surface; and when the electromotive force fell, there would be a source of electricity coming out to supply the mains at a lower voltage. It would thus soak in. Mr. Lane Fox wanted a constant current, not a constant electromotive force. He argued that the expression "electric force" throughout the specification meant current, and not electromotive force. Lord Justice Lopes thought this distinction was too fine. Lord Justice Kay said that they could raise the electromotive force by supplying more current; but Mr. Wallace replied that to do that they must have it at a higher electromotive force. In answer to a question, he admitted that this supply would prevent the electromotive force going further down. Lord Justice Lopes: "But that is regulation." Lord Justice Kay: "If it arrests diminution is not that regulation?" Mr. Wallace said that it tended to keep it constant. Lord Justice Lindley: "If you do a thing tending to make a thing more constant, is not that regulating?" Mr. Wallace: "It would be regulating it in one way, but not in another." Lord Justice Kay read regulation to mean keeping 100 volts. Mr. Wallace said that Lane Fox's object was not to supply volts but current. Lord Justice Kay: "But his object was to light the lamps." His lordship added that the current would be of no use if it were not sufficient to light the lamps, and that it must be used intelligently; he would not use electricity which would destroy the lamps. No workman in 1878 would fail to understand that. Mr. Wallace said that it was a question whether he would know it; he might damage the lamps. The point is that the workman would damage the lamps; but there were no lamps, and no experience in lamps. Lord Justice Lindley said that this might require a little practice and skill, but no invention. He put it to Mr. Wallace if a dynamo were running with the lamps lighted, if the belt slipped, there would be a draught upon the mains. Would this be supplied by the batteries even if they were not full? Mr. Wallace said there would be a sudden drop. Lord Justice Kay said that he understood that a battery might be too large because it would never be properly charged.

Mr. Wallace then turned to the disclaimer, and said that Mr. Lane Fox had left in the regulating, but had disclaimed the regulator. Lord Justice Lindley said that the nature of the invention was for keeping the electromotive force constant by the use of batteries and by a regulator. If he struck out the regulator that would not alter the invention. Lord Justice Kay observed that the regulator never entered into the fourth claim, and thought that this was a mere fight about words. Lord Justice Lopes asked why regulation should not apply to both batteries and regulator. Mr. Wallace replied that Lane Fox did not know until 1883 that batteries alone could regulate. Lord Justice Kay said that the regulator was only to regulate the speed of the dynamos, and was devoted solely to that. The batteries were entirely different. If there were a large draught on the mains, that would have nothing to do with the speed of the dynamo. Mr. Wallace replied, that if there were a large demand, that would cause the draught to drop and the electrometer regulator would work. Lord Justice Kay said that the instant there was a drop the battery would act before the regulator had time to act. Mr. Wallace explained that the draught would directly affect the speed of the dynamo.

Mr. Wallace argued that Mr. Lane Fox had not described the same invention in the provisional specification that he had done in the complete. Lord Justice Kay said that the patent was for "improvements," and that these were not all claimed in one claim, but each was claimed by itself. Mr. Wallace said that there was no regulating effect in the battery except by its inherent quality as a reservoir. In the provisional specification there was no mention of batteries for regulating. Lord Justice Kay said Lane Fox intended to have batteries as a reservoir, and found afterwards that they had an advantage which he did not then see, that they would keep the electromotive force constant. Mr. Wallace: "But at the time of the provisional he had not found that out." Lord Justice Lindley said that then if there had been no disclaimer there would have been no disconformity. Mr. Wallace contended that there would have been disconformity anyhow. The batteries were to be used in the first instance only as reservoirs. Lord Justice Kay asked what would be the use of it if not to supply a deficiency. Mr. Wallace replied that it would supply current, but not pressure. Lord Justice Kay said that it was involved in the word "reservoir" that he had this power; but that it was not all expanded in the provisional. He added that the Court was not forced to construe a provisional specification critically, and that they would not do so unless forced. The case of "Woodward *v.* Sampson" was cited by Lord Justice Lindley. This showed that an inventor was not bound to describe every mode in the provisional, but

Digitized by Google

if new modes were discovered afterwards he was bound to put them in the complete specification. Lord Justice Kay said that if another advantage were discovered, all that he then knew being given in the provisional, then if an additional one were found, there would be no disconformity. The battery was not changed, its position was not changed; but another advantage was added. Mr. Wallace: "Yes, and is claimed for, and this changes the nature of the invention." Lord Justice Lopes said that there was nothing new in the use of a battery as a reservoir, and that the regulating power had been described in the complete specification. Mr. Wallace said that the public had a right to use a battery as a reservoir. Lord Justice Kay: "But not for electric lighting of incandescent lamps." Lord Justice Lopes asked whether the invention was not in putting the mains and the battery together. Lord Justice Kay compared this invention to a watch with a peculiar escapement, it was claimed that it would go more regularly, but in the complete specification it was said that not only would it go more regularly, but it would last for years without cleaning. Mr. Wallace: "But Mr. Lane Fox did not invent the use of reservoirs." Lord Justice Lopes: "But the invention was the putting together of the batteries and mains and lamps."

"Harrison *v.* Cox-Walker" was cited, and evidence was read on the size of the cells. Mr. Wallace said that Mr. Lane Fox had neglected the "back volts," and thought that the large cells would reduce the internal resistance, and so allow of charging at lower pressure; but the back volt constituted 99 per cent. of the resistance. Mr. Wallace then summed up his arguments on Mr. Justice A. L. Smith's judgment as to infringement, disconformity, and that the invention was not workable.

Mr. Wallace then proceeded to open his cross-appeal against those points which had had been given by Mr. Justice A. L. Smith in favour of Mr. Lane Fox. He argued that the defendants did not infringe because they used switches, and because their batteries were concentrated at the station and not dotted about. The question of "earth" was then discussed at great length. Mr. Wallace said that although the earth was disclaimed, something was left in the specification which was bad. If it were granted that the specification directed that either the earth might be used as the return conductor, or another conductor might be used, the patent would be bad if the earth were unsuitable. "Simpson *v.* Halliday" was cited on this point. In that case a chemical process was described, and it was directed that it might be carried on with heat or without heat. One of these was impossible, and the patent had been held to be bad. Mr. Wallace denied that the term "earth" had any technical meaning in 1878. Lord Justice Kay asked why then, were inverted commas used. Mr. Wallace referred to the judgment of Mr. Justice A. L. Smith, who held the facts for the defendants, but the law against them, that is to say, that it was not an essential part of the invention. Mr. Wallace asked Mr. Lane Fox if he would admit Mr. Justice Smith's facts on the earth, but Mr. Lane Fox declined to do so. Lord Justice Kay said that it appeared to matter as little as if a man wore his hat on the right side of his head or on the left, on which one of the experts on the defendants' side remarked in an audible whisper, that he might have patented the wearing of it on the right-hand side, a comment which his lordship appeared to fully appreciate. Lord Justice Kay gave as an illustation the invention of a boiler in which the novelty was a number of pipes through which the fire might go. Perhaps a greater number than had ever been used before. It might be said in the patent that the draught must go through a chimney, and the size of this was described as 9in. square. It might be found afterwards that on a larger scale the area of the chimney must be greater. The inventor had not patented the chimney, but the boiler. Mr. Wallace interposed by saying that Mr. Lane Fox had not invented secondary batteries, and that, therefore, the illustration would not apply. Lord Justice Lindley said that there could not be effective distribution without some means of getting rid of that which had been distributed. Mr. Wallace said that if this hypothetical patent had been for a process of generating heat it would have been analogous to Lane Fox's patent. Lord Justice Kay said that it might be an invention for distributing heat in a boiler. They could not distribute if the passage were blocked.

SATURDAY, JULY 2ND.

Mr. WALLACE, in resuming his address on the cross appeal, said that when the Court adjourned they had been considering an analogy; he would not return to it, but would to a slightly different one. Suppose a steam engine, in which the steam, after passing out through the exhaust, was returned again into the engine. Anything which would stop the flow of steam could be injurious. This was the case with the earth. He then read extracts from the evidence about the use of the earth as a conductor. Mr. Wallace then turned to the absence of subject matter and anticipation. He said that the principle of parallel distribution was old, and that if Mr. Lane Fox would admit this he need not go on with this point. Mr. Lane Fox rose to say that there was not a word about parallel distribution in his patent. In so far as it was parallel it was not claimed. Mr. Wallace asked, what then was novel? It must be the use of batteries in connection with electric light. Lord Justice Kay said that it was for batteries used as reservoirs connected with lamps in parallel.

Mr. Wallace then turned to anticipation, and Lord Justice Lindley asked him how near he could come. Lord Justice Kay asked if there was anyone who had professed to keep pressure constant. Mr. Wallace said that there was no exact anticipation, but the examples he would give were to show the general knowledge on the matter before 1878. The systems of Clark, Breguet and others were mentioned. Mr. Justice A. L. Smith had dismissed these anticipations, but Mr. Wallace said that he was there to appeal against this. The patent of Achard was discussed, and Lord Justice Lindley said that, as far as they had got, there had been secondary batteries used as reservoirs for bells and brakes. Breguet's communication to *La Nature* was read, describing an arc light to be used at sea intermittently. Lord Justice Kay said that this was an approach, but a long way off Lane Fox. How much nearer could he get? Mr. Wallace then referred to Rapieff, and submitted that Lane Fox had made no invention. Lord Justice Lindley: "Although he succeeded in doing what nobody else had done?" Mr. Wallace: "But Lane Fox did *not* succeed." The defendants, he said, only used their battery to allow the station to be shut up at night. If they had no storage they would have to keep their staff there, and to keep the boilers, &c., at work all night, and in that case it would be impossible to earn a dividend. Lane Fox must have thought that his patent contained some further novelty, for he must have known that batteries had been used as reservoirs.

In dealing with the infringement, Mr. Wallace said that the real object of Lane Fox's invention was shown in Mr. Swinburne's diagram (*Electrician*, Vol. XXVIII., p. 548), particularly Case 3. Lord Justice Kay: "But that is construction," and added that he never allowed a witness to construe. Mr. Wallace said that it described what Mr. Lane Fox thought. Lord Justice Lopes: "You mean, what Mr. Swinburne thought Lane Fox thought," Mr. Wallace said that Lane Fox dotted his batteries about in order to reduce the size of the mains. Lord Justice Kay said that Lane Fox put certain things in the provisional, and when he came to the complete he recommended more. Mr. Wallace said that if he did that he smashed his lamps, spoiled his battery, with disastrous results.

When Mr. LANE FOX rose to reply, Lord Justice Lindley said that what they chiefly wanted to know was the exact nature of his invention, as everything would turn on that. Mr. Lane Fox said that he would do so, but would first say that he was going to deal with six points:—1. The nature and novelty of his invention. 2. The subject matter. 3. Utility. 4. Sufficiency. 5. Disconformity. 6, Infringement. He would first take the invention as described. The idea, he believed, was new. He wished for a source of power from which to distribute light, and with a variable number of lights, and yet have a constant available supply. He conceived the idea of a source of energy with which the current might vary, but the pressure remain constant, and this invention was a way of putting this into effect. The Edison patent for series lamps was subsequent to this patent, and it had been abandoned for further improvements. Edison's other patent was three weeks later than this, and was for a low-resistance lamp. Each was regulated independently. About one and a-half year later Edison patented the carbon filament This was on exactly the same lines as those suggested in his own patent, viz., high resistance, and the surface of the filament proportioned to the light to be given. The broad idea of his invention was the constant pressure. He did not rely on a generator and a steam-engine, and felt it was important to have some reserve, a kind of buffer, to equalise variations of pressure. Lord Justice Kay had suggested the analogy of a fire-engine in which an air cushion was used to give a constant stream. The Planté battery was well known, there was no need for him to describe it in his patent. A spring might be old, and yet might be applied to a novel purpose, but still it would take in force and give it out. If an inventor took a spring and a pendulum there might be no novelty in either; the action of a spring was well known, as, for example, in a bow and arrow, but these might be combined to form a clock; and the use of batteries in his invention differed as much from their former use as the spring of a bow differed from the spring in a clock.

Because an invention was simple it was not necessarily bad. It was well known that one could divide an electric current. An electric current used to be considered as a fixed quantity, and all efforts to divide it prior to his patent had been to split it up in the way in which the stream of a river divides round islands. But the idea of a constant pressure tending to develop currents was a new idea. He did not claim it as a principle, but he claimed means for carrying it into effect. His idea was that the pressure should be maintained, notwithstanding a draught upon the mains. He took high-resistance lamps and low-resistance mains. The battery was one means and the regulator was another.

Lord Justice Kay asked how Mr. Lane Fox distinguished current from pressure. Mr. Lane Fox replied that current was the result of a difference of pressure. Lord Justice Lopes asked a question about the hydraulic analogy, and Mr. Lane Fox expounded Ohm's law. Lord Justice Kay entered carefully on his notes from Mr. Lane Fox's dictation that current was proportional to electromotive force divided by resistance, and after that the matter of course dropped.

Mr. Lane Fox said that his invention was valuable by its simplicity, and cited a case in which a patent, though simple, was held to be good. Lord Justice Lindley observed that they were accustomed to simple inventions, and that Mr. Lane Fox need not deal with that. As to the practicability of return by earth, there were two distinct ideas. First, what is "earth"? and, secondly, how is it affected? He thought that there was no real disagreement here. "Earth" was a free path for the current. Telegraphists had for many years before this availed themselves of the conducting power of the soil. The term had thus become technical. He contended that *the* earth always meant the zero of potential. Lord Justice Kay asked if any known mode of return would do. Mr. Lane Fox proceeded to describe means of getting "earth." Sometimes telegraphists could not get it. If there were no earth at all, but dry sand, they could use a wire and call it "earth." If there was rock, earth-plates would not affect an "earth." If it were construed to mean soil, he would point to evidence which showed that 40 amperes would pass, and that that would be available for 100 or 200 lamps. On Fig. 5 of the specification (*The Electrician*, Vol. XXVIII. p. 438), there were less than a dozen lamps shown. That was only equivalent to four amperes. Dr. Hopkinson had admitted that it was possible to use 40. Lord Justice Lopes said that a skilled workman would know that if this failed he must use other means. Mr. Lane Fox said that "earth" meant a free path; if it were not a free path it would not be an "earth." Dr. Hopkinson's evidence showed that it would work on a small scale. He would not mind using 10 amperes; he would be uneasy with 100, and was positive that 1,000 could not be employed. Mr. Lane Fox compared these currents to the durability or

Digitized by Google

life of the filaments of glow lamps. A durability of 1,000 hours is required and expected in lamps to-day. But lamps were made for the purpose of a patent case, some eight or nine years after the date of the patent, in which the life was from 2 to 60 hours. On this evidence that patent was held to be valid, and this life was held to be sufficient.

On the question of utility, Mr. Lane Fox wished to call attention to two distinct points with reference to secondary batteries. The first was that according to Mr. King they could not help to keep the pressure constant at all, but, on the contrary, they would cause variations where variations would not otherwise be. Mr. King had described this in connection with what he had been pleased to call an example of his (the plaintiff's) mode of working. It was a complete fallacy, for he used a constant current of a fixed quantity. Under cross-examination he had said that suppose there were no batteries at all, and that a constant current of 80 amperes was passing through the lamps, there might be a variation of three volts when half the lamps were turned off; but if batteries were connected, there would be more irregularity in the pressure which might become illimitable. Mr. King had been cross-examined by the Attorney-General upon a passage which had been inadvertently read by Sir Horace Davey from a circular issued by Mr. King's firm. In this passage the batteries were said to act as regulators. Referring to Rapieff's patent, it consisted of plates immersed in an insulating liquid, while Planté's battery contained a conducting liquid. The second point on the question of utility was that batteries had an inherent regulating effect, and not as Mr. King said. The defendants used a large store for commercial purposes, and in order to get their batteries full, they must raise the pressure. He would admit at once that they could charge them thus if they wished to do so, if they had got switches. They would then, naturally, not take care about high volts, and would not use large surfaces. Witnesses had admitted that a small current goes in under a small pressure. Prof. Forbes had done so with five volts. The batteries would have to be enormous for charging with a difference of only 1 per cent. It was true that they would have to go to the point B when they stored a large quantity. Mr. Lane Fox then repeated his analogy of storing gas in an iron bottle. There was no point at which it could be said to be full, and the same was the case with a secondary battery. When they charged and discharged with a large difference of pressure, there was a great waste of energy, and the commercial question was, Is it better to incur this waste, or to spend more on the first cost of a large battery. In Dr. Hopkinson's evidence he had said that his battery on one occasion had discharged for four hours and five minutes without moving the switches working on "Lane Fox pure and simple." Lord Justice Lopes interposed with the suggestion that there might have been no demand for regulation during this period. The question was the sufficiency of regulation by a large battery not fully charged. An extract from Sir F. Bramwell's evidence was read by Mr. Lane Fox, in which he described a battery which regulated within the limits of pressure prescribed by the Board of Trade, 4 per cent. up and 4 per cent. down. Mr. Wallace rose to point out that it had not been charged under these conditions. Mr. Lane Fox then dealt with the bubbling which is necessary to keep a battery in health, and said that Prof. Barrett had had his battery for six years, and the running of the lamps and charging of the battery had been carried on simultaneously. Mr. Lane Fox explained that batteries suffered from sulphating, and that this took place more with a thick active coating on the plate than with a thin one.

Mr. Wallace put in a written summary of his arguments.

MONDAY, JULY 4TH.

Mr. LANE FOX, in continuing his reply, began by recapitulating the chief points of his case, but soon broke the thread of his arguments to take up and reply to various statements in the summary which Mr. Wallace had put in on Saturday. He said that the defendants had been at great pains to prove that whatever size of battery was used, a great difference of volts was necessary for charging. He contended that the difference of pressure varied as the strength of the current, and had a relation to the surface of the plates. His evidence showed that when a large difference of potential was used to charge batteries, there was a great waste of power or energy. The more closely the voltage of charging and discharging approximated to each other, the more economical would be the working. This was well known to Planté. In speaking of charging with a large current, he did not mean a large current *per se*, but relative to the size of the battery or to the size of the installation. Within proper limits of plate area, they could charge and discharge with a small potential difference. It was admitted by the defendants that some current would go in and out. If he were not hampered by commercial considerations of storage, the batteries might be utilised to the best advantage. Sir F. Bramwell had said that the defendants could not earn a good dividend if they had gone to the expense of a battery five times greater than their present one. In Mr. Crompton's evidence it was stated that the defendants' batteries had 30 times as much active area as a Planté of the same size, but he did not want active area, but conducting surface. The point B, to which reference had so frequently been made, was only an imaginary point on a hypothetical curve. Mr. Crompton had said that this curve did not apply to his battery. There was no reason at all why 110 volts should mean 2·2 volts per cell. It might just as well be obtained by 55 cells at two volts each. It was said that the lamps would break at 110 volts, why not let the point be 100 volts, and use 100-volt lamps? But if there were any special virtue in 110 volts for the batteries, why not use 110-volt lamps? Why not keep both mains and batteries always more or less at 110 volts. According to the defendants' evidence the current would flow in and out readily at 110 volts; let them always charge and keep the batteries, then, at 110 volts, or use 45 cells and keep them at 100 volts. Referring to the summary handed in by Mr. Wallace, Mr. Lane Fox said he would reply to the statements contained in it. Lord Justice Lindley said that he had perhaps better conduct his case in his own way; and in reply to Mr. Lane Fox, Lord Justice Lindley said that he might draw up and put in a similar statement. On another suggestion that he need not attend further to this summary, Mr. Lane Fox said that he was not a bit afraid of it.

He said that Mr. Crompton had used 33 cells at the Law Courts and 59-volt lamps. The cells had been charged high, and they would have about 2·2 volts per cell, making 70 volts in all. These had been suddenly turned on to the 59-volt lamps, and, of course, they burned too bright. The brilliancy continued, according to Mr. Crompton's evidence, for about 20 minutes, or perhaps more. The high pressure did not, therefore, fall in a few seconds, as had been suggested. Mr. Wallace rose to say that they had dropped at once; the drop *had* taken place. Mr. Lane Fox referred to a discrepancy between the evidence of Prof. Kennedy and that of Mr. Millar. Prof. Kennedy had said that the cells regulated well with only a small variation in the number of the lamps; but Mr. Millar had said that they would not regulate at all with a small number, but would do so with a large number.

Continuing to comment upon disconnected points in Mr. Wallace's summary, Mr. Lane Fox said that the pressure was forced up in charging because a large current was being pushed in; the batteries became choked with it, and therefore the pressure became high. But if it were not pushed so rapidly the charging voltage would almost coincide with the statical voltage. Mr. Lane Fox alluded to the practical use of the present system of switches to Lady Conyers' ball, and remarked that switches were not used there, and he added that they were not used at the St. James' and Pall Mall station. He went on to explain and to discuss the chemical changes which went on in charging and discharging a battery. If the cell were empty, and there were only two or three volts right at the bottom of it, the resistance of that cell, Mr. Lane Fox said, would be very small. He again alluded to the storing of gas in an iron bottle under pressure, and said that if gas were compressed slowly there would only be back pressure; but if the pressure were rapid, there would also be friction, caused by the flow of gas in the pipe, and this was analogous to the internal resistance of the battery. He cited the aniline dye case, to show that the pecuniary success of an invention had no relation to its utility. After several disconnected references to points in Mr. Wallace's summary, Mr. Lane Fox said that the defendants infringed when the switches were standing in any position, and they only ceased to infringe while the switches were being moved. It was as though they infringed on the ground floor, infringed on the first floor, and infringed on the second floor, but not while they were going up and down stairs. It was easy enough, when the broad outline of an invention became known, to carry out modifications. The use of feeders was one such modification, and this was a subject of one of his own patents. He cited "Thomson *v.* Batty," an action for infringement of a patent of Sir William Thomson for ships' compasses. Long after these compasses—which were a God-send to sailors—had been invented, they were found wanting in a certain respect; but this did not prevent Sir W. Thomson from improving on his own patent. Mr. Lane Fox then drew their Lordships' attention to the last portion of Mr. Wallace's summary, and without reading it, said it was surprising that Mr. Wallace should not know about this matter, since he was a Director of the defendant Company. No evidence had been brought against him as to sufficiency. No experiments had been carried out to work the invention, as it had been described, to show that it could not be carried out; but evidence had been given to the opposite effect. He did not know if he had pointed out that in Ayrton's curves the largest current had been used that the manufacturers could recommend as advisable. Mr. Lane Fox concluded by thanking their Lordships for the consideration which they had given to his case.

Mr. WALLACE rose to offer some reply on the cross appeal, but was informed that nothing further was necessary.

Mr. LANE FOX asked if it were likely that judgment would be given soon, as he had a petition before the Privy Council for an extension of his patent.

Lord Justice LINDLEY said that the judgment could not be given sooner than a fortnight.

Lane-Fox Petition before Privy Council for Extension of Patent.

Mr. St. G. Lane Fox's petition for prolongation of his patent rights (No. 3,988, 1878) came before the Judicial Committee of the Privy Council on Thursday.

The petitioner appeared in person. Mr. Wallace was counsel for the respondents (the opposers); and Mr. Sutton represented the Crown.

At the commencement of the proceedings it was pointed out to the petitioner that he had failed to lay before the Committee detailed accounts showing the amount of remuneration which the patent had brought to him from every point of view.

Mr. LANE FOX replied that he could call evidence on that point, and asked their lordships not to confine themselves very strictly as to the details in connection with the accounts. He said he had derived no advantage from his invention, although it was admitted that large industries had grown up out of it.

The opposers called attention to the fact that the patent had been declared invalid in the Court of Chancery; but the Committee replied that they were not concerned with the validity of patents.

After some discussion the Committee decided that inasmuch as Mr. Lane Fox had failed to produce the proper accounts showing the amount of remuneration he had derived from his patent during its eight years' working, and that being an indispensable condition which had been imposed on persons seeking an extension of their patent rights, the petition must be dismissed.

The petition was accordingly dismissed.

In re Joseph Slater Lewis.

The public examination in bankruptcy of Joseph Slater Lewis, described as an electrical appliances manufacturers' manager, of Middlesex, and lately carrying on business at the National Telegraph Works, Wainwright-street, Aston, and residing at the Swifts, Yardley, was fixed to take place at the Birmingham County Court, on Thursday last week, before Mr. Registrar Cole. The liabilities were stated at £1,613. 18s. 7d., and assets *nil*. Mr. J. A. Etches (Whitchurch) represented the bankrupt; and Mr. Hugo Young (instructed by Mr. Isaac Bradley) appeared for Messrs. Archdale and Co., the petitioning creditors.

Mr. WOOLLETT (the Assistant Official Receiver) applied for an adjournment, as certain accounts had not been filed, and an investigation of them had consequently not been made.

Mr. ETCHES opposed the application, remarking that he understood the Official Receiver did not find fault with the accounts not being filed, but the bankrupt had not separated the private from the trade accounts. He should at all events like to ask the bankrupt certain questions, which he wished to be brought before the Court, in reference to his failure.

The REGISTRAR pointed out that the accounts were not only supposed to be filed for the convenience of the Official Receiver, but also that any creditors might inspect them.

Mr. WOOLLETT said he thought a week would be ample time.

Mr. ETCHES: Then there is the election, and I could not attend here.

The REGISTRAR: This Court has nothing to do with the election—(laughter).

The bankrupt said he desired the matter over as quickly as possible, for certain things were hanging over his head which were acting to his very serious prejudice.

Eventually it was decided that the examination should be adjourned until July 25th.—*Birmingham Gazette.*

SCANDINAVIAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

COPENHAGEN, *June* 25, 1892.

Among the smaller Swedish towns adopting the electric light is Helsingborg, which has just erected a central electric station, close to the new harbour. The full capacity is estimated at 2,000 16-c.p. lamps, although the plant at present installed only amounts to 100 H.P. The three-wire system is employed, without accumulators. The cables are underground, and are of the Siemens and Halske iron-hoop protected lead-covered pattern.

The State Telephone in Sweden has issued its seventh list. There are now 5,604 subscribers, against 3,176 subscribers in its former list of July 1st last year, showing an increase in ten months of 2,428 subscribers. The Christiania Telephone Company last year increased its number of subscribers by 376, the total of telephones in use at the end of 1891 being 3,280, as against 2,817 the year before. During 1891 4,682,843 conversations were held through the Christiania exchange, being 1,428 conversations per subscriber per year, the average for week days being 15,136. A new telephone tower has been built, with accommodation for some 4,000 aerial wires and about 5,000 cables. The receipts amounted to 254,208kr., against 222,397kr. last year. The net profits were 69,000kr., of which the shareholders get 6 per cent. The share capital has now been doubled, and amounts to 1,500,000kr.

The electric lighting of the principal square of Copenhagen has now been completed, and works exceedingly well. The standards for the arc lamps are very ornamental, although they cannot vie with those placed at a portion of the pier, which are very elaborate. At the recent illumination on the occasion of the Golden Wedding of the King and Queen of Denmark, a number of temporary electric light arrangements were installed, and gave universal satisfaction.

CORRESPONDENCE.

NEGATIVE RESULTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With the general tenour of your remarks on page 209 I, of course, agree; but there are just one or two details which it may be worth while to emphasise.

You question whether we can ever induce nature to say "no." If we ask unreasonable questions it may, indeed, be impossible; but if we ask reasonable ones, it is easy to get a definite answer. To the question, "Does light travel as slowly as sound or bullets?" the ancient experiment with dark lanterns could readily reply, "No, very much quicker." To the question, "Does light travel at an infinite pace?" it could answer nothing. The question, "At what rate does light travel?" it could not answer; but that is not a question to be answered by either yes or no.

I submit that "a measure of magnitude, however rough," is not always and necessarily more satisfactory than a definite failure to find any magnitude to measure. For if the possible error is 100 per cent., we may very possibly be seeming to measure something which is really non-existent.

Thus, in the early part of the century many attempts were made to determine the parallax of the fixed stars, and many apparent results were obtained. But the more care taken the smaller these results became, and some of them gave a parallax less than nothing, making the stars further than infinity!

Again, before the time of Bradley it was comparatively easy to get apparent parallactic observations of zenith stars; but they were spurious, and were shown by Bradley to be spurious, being due to the finite velocity of light and to an undiscovered motion of the earth's axis. Their periodicity (one year and 19 year periods) in this instance distinguished them from the genuine phenomenon; which last indeed is now observable, although so extraordinarily minute (half a second at most). It must, I think, be admitted that, under these circumstances, a definite failure to detect any parallax so great as one second of arc would have been a result more valuable and more difficult to secure than a "measurement of its magnitude, however rough" (say two or three seconds out).

Similarly with regard to the possible drag of ether by matter. If the question asked is "Does moving matter drag ether infinitesimally with it?" that cannot be answered. But if the question asked be, "Does a moving sheet of steel drag ether a tenth of an inch away from it with its own speed, or with as much as one-tenth of its own speed?" experiment has answered, "No, nor yet with as much as one-hundredth of its speed." And the difficulty was to secure this negative result. It was easy enough to get positive results; results, moreover, of reasonable, and by-some-expected magnitudes; but all these had to be hunted down and traced to their several spurious sources before it could be clearly asserted that the answer, down to a certain finite limit of accuracy, was in the negative. To expect an infinite accuracy in the answer 0 is as unreasonable as to expect an infinite accuracy in an answer like 52,871.

I do not think that anything I have said is of the nature of controversy. I write because I am glad of the opportunity you have kindly afforded me to remove so far as possible what seems to me a slight misapprehension, which appears rather prevalent, concerning the value of a definite and specific and numerical "negative answer."—Yours, &c. OLIVER J. LODGE.

THE "AMPERE-CENTIMETRE."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of June 3rd you reprint my Paper on the "Ampere-Centimetre, a Measure of Electromagnetism," to which you have added some interesting and able editorial comments on page 113. It seems to me, however, that your criticisms in the third paragraph on page 108 are very unjust, and even incorrect, as will appear evident from your two subsequent paragraphs, and from the original Paper. You say that the "error" in my argument lies in the assumption that K is a constant. It appears, however, that K *is* a constant for circles (and therefore also for a straight line or infinite circuit), which is the only sense in which I use it; and I stated this clearly in the article. It was a mistake on your part to assume that I applied K to anything but a circle. You say it "varies very much for different sizes and shapes of the circuit." It does *not* vary at all with the size of the *circle*. It is, of course, not constant for different *shapes* of circuits, that is, different from a circle; but nowhere did I assume it was. I am well aware that the self-induction of the circuit changes with its shape, and nowhere do I say or assume the contrary. It would not have been an unwarranted assumption on your part to have assumed that I knew this. I admit that it was an unfortunate oversight on my part not to have added the word "circular" before "circuit" or coil in the sixth paragraph of my Paper, but it seems to me this might have been inferred from the rest of my Paper. Magnet coils in practice are usually circular, or nearly so, and my remarks had reference to such coils; but I admit it ought to have been more clearly stated.

In the same paragraph you speak of the effect of iron in varying this constant K. This is clearly met in the first part of my Paper. You also state that "it is quite erroneous to

Digitized by Google

assume that the number of lines of force produced by the current flowing in a circuit is proportional to the number of amperes multiplied by the number of feet of wire composing the circuit." While in the very next paragraph you show that the conditions under which it does hold "are all very nearly fulfilled in the manufacture of any given type of machine." If this second statement is true, the first is certainly not just or fair criticism, at all events it does not seem consistent on your part. If the Paper is worthy the favourable comment you make, it would hardly seem to deserve the condemnation which you give in such superlative terms.

The intention of my Paper was to endeavour to prove, or at least to start a discussion which would prove or disprove the fact that a unit current, considered apart from its return path or from magnetic material, represents a fixed and definite number of lines of force for every unit length of its path. When a circuit is doubled on itself, as it always is in any closed circuit, there will be a joint action of two opposite circuits, which action will evidently depend on the relative positions of the parts of the circuits. I merely thought that by starting with the ampere-centimetre as a sort of unit, some problems in electromagnetism might possibly be simplified. Furthermore, the principle announced does seem to be true for circular coils, and as most magnet coils are circular or nearly so, it might be applied to most of the practical cases, as you yourself have shown. My object was merely to make a suggestion, hoping it might be of use to someone.—Yours, &c., CARL HERING.

June 18, 1892.

[We still think our former criticisms fair. We never supposed our valued correspondent to be ignorant of the fact that the self-induction of a coil is dependent on its shape. It is, however, quite possible to be aware of a fact, and yet to argue in a manner which can be shown to be inconsistent with it. The two quotations in the above letter in no way contradict each other. Some further comments will be found in our "Notes" column.—ED. *E.*]

SUSPENDED *v.* STATIONARY COIL GALVANOMETERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of July 1st there is a letter by a Mr. Flower which ends as follows:—"Comparing these figures with the results given above, the immense superiority of the Thomson over the d'Arsonval galvanometer (as far as sensitiveness is concerned) is obvious. The statement made concerning the latter instrument is, therefore, utterly misleading, to say the least of it." Probably your readers will have already detected the collection of errors in Mr. Flower's letter which have led him to this conclusion; but, as he has been so ill-advised as to base a grave charge on his incorrect reasoning, it may be advisable to place his errors on record.

He quotes our statement that a certain d'Arsonval galvanometer of 300 ohms resistance gave a deflection of 95 divisions per micro-ampere on a scale placed at a distance of 2,000 scale divisions. To this statement he raises no objection; but he says that, from tests he has made, a Thomson galvanometer constructed by Messrs. Elliott, and having the same resistance and a periodic time of 4·5 seconds, would give the same deflection with $\frac{1}{110000}$ ampere, and he deduces from this "the immense superiority of the Thomson over the d'Arsonval galvanometer." Is this because he does not know that a micro-ampere means the millionth of an ampere, or can it be that he is not aware that $\frac{1}{1000000}$ and $\frac{1}{110000}$ only differ by one-tenth part?

But had these two instruments the same periodic time? No; the periodic time of the Thomson galvanometer was 4·5 seconds, while that of the d'Arsonval galvanometer, as stated on the label attached to this instrument, was 4 seconds. (The 5 seconds attributed to this instrument by Mr. Flower is a mere assumption.) Consequently, had the Thomson galvanometer been adjusted to have the same periodic time as the d'Arsonval galvanometer, the current of $\frac{1}{110000}$ ampere, given by Mr. Flower, would have been increased to $\frac{1}{87000}$ ampere, which is, actually, 15 per cent. greater than the one micro-ampere required by the d'Arsonval instrument.

We may, however, go even farther than this; for, as stated in the Abstract (see *The Electrician*, page 175) the decrement is *13 on open circuit*—that is to say, the second swing is only one-thirteenth of the first, or this instrument is practically dead beat *even on open circuit*. Now this damping lengthens the periodic time by about 33 per cent., so that if the silver damping tube attached to the coil were replaced by one of manganin the periodic time would become only 3 seconds instead of 4. If, then, the two instruments be arranged for equal damping as well as for the same resistance of 300 ohms and the same periodic time, the d'Arsonval instrument has not merely the same sensibility, but a far greater sensibility than that possessed by a 300-ohm Thomson galvanometer as given by Mr. Flower.

In what way, however, has Mr. Flower ascertained the sensibility of a 300-ohm Thomson galvanometer when the periodic time is five seconds? Why, by using the following startling law:—"In Thomson instruments of similar construction their figures of merit are fairly proportional to their resistances." Consequently, the resistance of a coil of given volume is proportional to the number of turns it contains. We thought that even a tyro knew better than this.

As a matter of fact, the sensibilities of galvanometers of similar construction, and adjusted to have the same periodic time, are about proportional to the square roots of their resistances when these resistances are low, and to their resistances raised to the power two fifths when high; (*see* our Paper on "Galvanometers," p. 92, *Proc. Phys. Soc.*, July, 1892). Mr. Flower is, therefore, but a sorry champion of the Thomson galvanometer, for he has much understated its sensibility. Indeed, if his tests of the 1,830-ohm instrument may be taken as correct, a 300-ohm Thomson galvanometer will be about three times as sensitive as his erroneous calculation makes it out to be.

Well, at any rate, he will say, even if my calculations be all wrong there is still something in my statement regarding "the immense superiority of the Thomson over the d'Arsonval galvanometer." Unfortunately for Mr. Flower, even when the Thomson galvanometer is credited with its true sensibility, and not with the smaller sensibility that Mr. Flower calculates for it, his sweeping statement remains just as untrue when equal damping as well as equal resistance and periodic time are considered. And in case he may not realise the correction that has to be made for damping we would refer him to the performance of the undamped d'Arsonval galvanometer that we also exhibited at the meeting of the Physical Society, but to which Mr. Flower makes no reference. This instrument has 13 ohms, a periodic time of 2·7 seconds, and gives a deflection of 74 scale divisions per micro-ampere. Now let us compare with this, not the sensibility erroneously calculated by Mr. Flower for a 300 ohm Thomson galvanometer, but the actual result which he says he obtained with an 1,830-ohm instrument. The periodic time was 4·5 seconds, and a deflection of 90 scale divisions was obtained with $\frac{1}{7340000}$ ampere. Hence, if this instrument were wound so as to have a resistance of 13 ohms, and if the controlling magnet were adjusted so that the periodic time were 2·7 seconds, it would give for one micro-ampere a deflection of

$$7{\cdot}34 \times 90 \left(\frac{13}{1830}\right)^{\frac{2}{5}} \left(\frac{2{\cdot}7}{4{\cdot}5}\right)^{2}$$

that is, 33 scale divisions.

Hence this d'Arsonval instrument is about $2\frac{1}{4}$ times as sensitive as Mr. Flower's "immensely superior" Thomson galvanometer.

It is to be observed that in selecting the power $\frac{2}{5}$ in preference to $\frac{1}{2}$ we have employed the power most favourable to the Thomson galvanometer, since, if the power $\frac{1}{2}$ had been used in the calculation given above, the result would have been that one of the d'Arsonval galvanometers exhibited by us at the Physical Society was nearly 4 times as sensitive as the Thomson instrument tested by Mr. Flower.—We are, &c.,

W. E. AYRTON.
T. MATHER.

TESTS OF TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the remarks in this week's number of *The Electrician* in reference to Dr. Hopkinson's transformer tests, it is stated that some of the transformers give an efficiency of 85 per cent.

Digitized by Google

at quarter load, and 97 per cent. at full load. The further statement is then made that these transformers, when working at full load for six hours and open circuit for eighteen hours, give a day efficiency of 92 per cent. "This," it is added, "will occasion surprise."

I must humbly confess it has very much surprised me, as it is obvious that, if the above statement is correct, there must be less waste in a transformer when open circuited than when it is at quarter load. I am sure that if this could be demonstrated all the alternating-current supply companies would be highly delighted, since at present they are mostly suffering from the idea that the opposite is the case.—Yours,

London, June 30, 1892. R. N. LUCAS.

CARBON BRUSHES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I observe in the last number of your journal an article dealing with carbon brushes for dynamos; and you seem to draw the conclusion that whilst they are widely used on the Continent, they have up till the present met with little favour in England. On the contrary, I can assure you that I have exported to England, through the agency of Mr. N. G. Thompson, of 13, Victoria-street, considerable quantities of these brushes; and I am in a position to state that English manufacturers have used them with success, since trial orders have invariably been followed by others of greater importance.

The objections which you offer to their general use, founded on the changes necessary with the old types of machines, are in the main perfectly fair but unimportant when we consider the small expense incurred and the results obtained.—Yours, &c.,

Paris, July 4, 1892. J. A. BERNE.

[The fact still remains that we sent a representative to the Crystal Palace Exhibition for the express purpose of examining and reporting upon the dynamo brushes, and that he failed to see a single specimen.—ED. *E.*]

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the paragraph in your issue of June 24th relating to carbon brushes, we fully endorse your remarks on the subject. It may interest you to know that we have used carbon brush gear on a very large number of our motors during the last two years, and in every case it has given satisfaction. We have found carbon superior to any other description of brush for motors requiring frequent reversal, having applied them successfully to tramcar, launch, crane, winding gear, and other motors.—Yours, &c.,

THE GENERAL ELECTRIC POWER AND TRACTION CO. (LIMITED),
THOS. SMITH, Secretary.

New Broad-street House, 35, New Broad-street,
London, July 6, 1892.

[Our remarks on this subject were not intended to be very laudatory; but, as they have called forth so many comments, we should be glad to hear if carbon brushes have ever been used to carry as much as 100 amperes, and to learn the dimensions necessary for collecting this current without heating.—ED. *E.*]

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have used carbon brushes from Levallois Perret on two installations I put up for my firm, one a King Brown, and the other a Crompton dynamo. In both cases they have answered perfectly, and kept the commutator in beautiful condition. Nor have I found the trouble you suggest in their current-carrying capacity. We also use them on a small Siemens at our works.—Yours, &c., RUSSELL.

Maidenhead, July 6, 1892.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1892.—The tenth annual edition of the above well-known annual is on sale, price 7s. 6d.; post free, in the United Kingdom, 8s. 3d.; abroad (a few countries excepted), post free, 8s. 10d. A digest of the contents will be sent on application.

TRADE NOTES AND NOTICES.

TENDERS INVITED.—The Committee of the Co-operative Wholesale Society (Limited) announce in our advertisement columns that they are prepared to receive tenders for the electric lighting of their warehouses and offices in Waterloo-street and Thornton-street, Newcastle-on-Tyne. Specifications and all information can be obtained from the society's engineer, Mr. John Thompson, C.E., Post Office-chambers, Newcastle. Tenders are to be delivered at the society's offices, Newcastle-on-Tyne, or or before the 19th inst.

———The Lighting Inspectors of Watlington (Oxon) invite tenders for lighting streets, roads, and other places in the parish either with oil, gas, or any other material. Tenders should be sent at once in a sealed letter, addressed to Mr. Richard Spyer, the Treasurer, at the office of the Inspectors, Market-p'ace, Watlington, of whom particulars may be obtained.

TENDERS RECEIVED.—The following were the tenders received by the Southampton Harbour Board for the supply of two electric cranes:—

	Cranes.	Accessories, mains, &c.	Total.
Keys' Electric Company (Limited).	£2,700	... £1,175	... £3,875
Crompton and Co. (Limited)	3,209	... 234	... 3,443
J. G. Statter and Co.	2,100	... 287	... 2,387

As mentioned in the last issue of *The Electrician*, p. 235, the tender of Messrs. J. G. Statter and Co. was accepted.

APPOINTMENT VACANT.—The Corporation of Blackpool invite applications for the appointment of a resident electrical engineer in connection with the scheme of electric light installation. Applications must reach Mr. T. Loftos, the town clerk, on or before Wednesday, the 20th inst. Further particulars will be found in our advertisement columns.

BARNET.—Messrs. H. F. Joel and Co. inform us that the award in the arbitration between themselves and the Barnet Local Board, in which they claimed compensation for breach of contract, was taken up by them on Friday last, June 30th, and was entirely in their favour. They obtain £500 as damages, and their costs in the reference, and the costs of the award.

PERSONAL.—Messrs. Fuller and Tate, late of the Brush Engineering Company, have gone into partnership, and commenced business at 20, Bucklersbury, as electrical and mechanical engineers.

VAUGHAN-SHERRIN ELECTRICAL ENGINEERING COMPANY (LTD.).—Claims against this Company (in voluntary liquidation) must be sent to the liquidator, Mr. S. Hedges, 15, George-street, Mansion House, E.C., by the 29th inst.

ELECTRIC APPARATUS COMPANY (LIMITED).—A meeting of the shareholders in this Company (in voluntary liquidation) will be held at Mr. John Annan's, 1, Walbrook, E.C., on the 8th prox, at 11 a.m., to receive an account of the winding-up.

DEED OF ASSIGNMENT.—A deed of assignment for the benefit of his creditors was filed on the 1st inst. by Herbert William Hooper, electrical engineer, of 17, Princes-street, Hanover-square, London, W., and Rowland Lodge, Epsom. The secured liabilities are £300, and unsecured £967. 12s. 6d.; and the assets, after deducting secured claims, are set down as £615. 6s. 6d.

LE CARBONE.—A company with this title has been formed to acquire the business of Messrs. Lacombe and Co., carbon makers, of Levallois-Perret, near Paris.

BENHAM AND FROUD (LIMITED).—To celebrate the jubilee of Mr. Froud's connection with the well-known Chandos Metal Works (which were established so far back as 1785), the chairman of the Company invited the directors and a select party of gentlemen immediately connected with the company to dine at the Crystal Palace on the 30th ult., the occasion forming also a pleasant termination to the labours of some of their number in connection with the Electrical Exhibition. By a coincidence one of the braziers in the employ of the firm also attains his jubilee of work this month, and the event was fittingly marked by a presentation during the afternoon.

COLLIERY LIGHTING.—The General Electric Power and Traction Company (Limited) have received instructions to light the New Hemsworth Colliery, near Halifax. The plant consists of a 300-light dynamo, and the necessary wiring and fitting.

ELECTRIC WIRES AND CABLES.—Messrs. W. T. Glover and Co send us a very well-arranged price-list of their manufactures, including vulcanised wires and cables, lead-covered, concentric, and armoured cables, flexible cords for ship use, twin flexible, and wire for fittings, flexible cable for dynamos, fuse and jointing wire, &c. They introduce a system of reference numbers, which seems to offer some advantages. 71653, for example, means 7 strands of No. 16 gauge of class No. 53. Various tables and formulæ make this a very useful catalogue.

ELECTRIC LAUNCH.—The "Florentia," an electric launch, by Mr. Sargeant, had her trial trip at Twickenham last Friday.

Digitized by Google

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

June 16, 1892.

11,277. G. A. GOODWIN and H. FOSTER. London. Improvements in electric current meters.

11,302. F. H. NALDER, H. NALDER, C. W. S. CRAWLEY and A. SOAMES. London. Improvements in electrical measuring instruments.

11,316. G. W. VIANEN. London. Improvements in or connected with electric alarums.

11,320. C. VOGT. London. Improvements in telephonic apparatus.

11,326. R. H. COURTENAY. London. Improvements in tubes or pipes for aeration drainage and electrification for horticultural purposes.

June 17, 1892.

11,344. F. B. NICHOLSON. London. Improvements in casing for cables and wires.

11,353. D. J. MULLAKY. Bradford. Improvements in electrical alarum clocks.

11,382. H. NIEWERTH. London. An improved process for manufacturing compound and elementary bodies or chemical products by means of electricity, and apparatus therefor.

11,393. F. WYNNE. London. Improvements in or relating to electric railways.

11,403. W. T. GOOLDEN and L. B. ATKINSON. London. Improvements in electric generators and motors.

June 18, 1892.

11,424. G. C. DYMOND. Liverpool. Improvements in automatic telephone and other electric exchanges. (Almon B. Strowger, United States.)

11,426. G. C. DYMOND. Liverpool. Improvements in or relating to indicating electric switches and current reversers. (Almon B. Strowger and W. S. Strowger, United States.)

SPECIFICATIONS PUBLISHED.

All Specifications price 8d.

1891.

11,113. LAHMEYER. Electromotors, &c.

12,525. GRIMSTON and DYKES. Electrical steering gear.

13,250. WHEATLEY (Ashfalck). Electrical switches, &c.

13,331. KELLOGG. Telephony.

1892.

5,631. JOHNSON (Hiss). Electrically-controlled elevators.

6,722. DONALDSON and MACRAE. Secondary batteries.

7,415. DEWEY. Electric propulsion of vehicles, &c.

8,535. FOWLER. Electrical hose-signalling apparatus.

COMPANIES' MEETINGS & REPORTS.

India Rubber, Gutta-Percha and Telegraph Works Company (Limited).

The half-yearly general meeting of this Company was held yesterday at the Cannon-street Hotel; Mr. S. W. Silver presiding.

The SECRETARY (Mr. William J. Tyler) having read the notice calling the meeting,

The CHAIRMAN said: I take the opportunity of informing you that the issue of new shares referred to when we last met has been satisfactorily carried out. This addition of capital, which was readily taken up, has greatly strengthened our position. The amount of general sales was increasing. We have manufactured and despatched the cables, and the ss. "Silvertown" is now off the coast of Brazil, engaged in laying the cables across the Atlantic to the West Coast of Africa. I may add that the works, machinery, &c., are in excellent order and equal to any demand that may be made. I beg to move, in accordance with the notice calling the meeting,—

"*That an interim dividend of 5 per cent. be paid forthwith.*"

The MANAGING DIRECTOR (Mr. Matthew Gray) seconded the motion, which was carried unanimously without discussion.

Mr. TREBLE moved, and Mr. MARTINDALE seconded, a vote of thanks to the Chairman and Directors, which was cordially passed.

The CHAIRMAN, in returning thanks, said that this renewed mark of confidence on the part of the shareholders would tend to increase the efforts of the Board to promote the prosperity of the Company.

The proceedings then terminated.

National Telephone Company (Limited).

The following is the report of the Directors for the year ending April 30 last, to be presented to the shareholders at the twelfth ordinary general meeting of the Company, to be held at the Cannon-street Hotel, on Thursday next, 14th inst., at 12 o'clock noon:—

The income accrued in respect of the business of the year amounts to £463,741. 5s. 4d., as compared with £431,112. 11s. 11d, for the preceding year, being an increase of £32,628. 13s. 5d.

The working expenses and other charges (excluding debenture and other interest) amount to £236,252. 0s. 5d., as compared with £199,483. 15s. 8d. for the preceding year, being an increase of £36,768. 4s. 9d.

The net result for the year, after deducting the Post Office royalties, amounting to £40,239. 5s. 8d., is a profit balance of £187,249. 19s. 3d., as compared with a balance of £195,047. 3s. 11d. for the preceding year, being a decrease of £7,797. 4s. 8d. It must, however, be remembered that at the end of 1890, in view of the expiration of important patents, a reduction of the tariffs in most of the Company's districts was carried into effect. Upon the business of the past year, this reduction has been equivalent to a cession of about £55,000 to the subscribers.

Further attention may be called to the fact that the rentals carried forward this year for unexpired terms of running contracts amount to £234,370. 11s. 2d., as compared with £204,431. 15s. 4d. for the preceding year, or an increase of £29,938. 15s. 10d.

Out of the divisible balance, after providing for interest on Debenture Stock, an interim dividend for the first half-year has already been paid at the rate of 6 per cent. per annum on the first and second preference shares, and 5 per cent. per annum on the ordinary shares. The Board will recommend the payment of a further dividend for the last half-year at the rate of 6 per cent. per annum on the first and second preference shares, and 7 per cent. per annum on the ordinary shares, making, with the interim dividend, 6 per cent. for the year.

The Board propose, under Article 113 of the Articles of Association, to transfer to reserve account £10,000, which, with £1,127. 3s. 6d. placed to reserve during the year from premium account, will bring up the amount of the reserve fund to £104,627. 3s. 6d.

The Directors have acquired on advantageous terms the telephonic business of the Caledonian Telephone Company (Limited) and of the Sheffield Telephone Exchange and Electric Light Company (Limited). A provisional agreement has also been recently entered into for acquiring the undertaking of the Western Counties and South Wales Telephone Company (Limited).

The Government have recently determined upon a policy under which it is proposed that all the trunk lines used for inter-town telephonic communication shall become the property of and be worked by the State, the exchanges and local service remaining in the hands of the companies for the term of their present licences. An Act confirming this policy and granting the necessary powers has just been passed by Parliament. Under its provisions the trunk lines of this Company can be acquired by agreement for money payment and other adequate compensation. The Board, after much anxious consideration, have decided that, as licensees of the Postmaster-General, it will be their duty, on fair terms, to co-operate loyally with him in giving effect to a policy having for its express object the expansion and improvement of the telephone service of the Kingdom, hitherto so seriously hampered and retarded for want of sufficient legal powers for carrying out such works as are absolutely essential if efficiency is to be attained. With this object in view, negotiations with the Government are now pending.

Since the last annual meeting the Company has suffered a severe blow in the death of its late President, Mr. F. R. Leyland. His colleagues on the Board desire to express their sense of the great loss which they have sustained by his death in being deprived of a valued coadjutor and friend. To fill the vacancy thus caused the Board have appointed Mr. George Franklin, of Sheffield, as a Director, with a view of securing representation on the Board of one of the most important commercial centres of the undertaking. The magnitude of the Company's business has rendered necessary the appointment of a general manager, and the Board have secured the services in that capacity of Mr. W. E. L. Gaine, who resigned the office of Town Clerk of Blackburn to take the position. The following Directors retire at this meeting, and being eligible offer themselves for re-election, viz., Mr. James Staats Forbes, Colonel Robert Raynsford Jackson, Mr. Eli Heyworth, and Mr. Samuel Herrick Sands. The auditors, Messrs. Welton, Jones, and Co., also retire, and are eligible for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

BRYNCELYN (PONTARDAWE) GASLIGHT AND COKE COMPANY (LIMITED).—This Company was registered on the 30th ult., with a capital of £1,500, in £10 shares, to light the parishes of Llanguicke and Killyhe bill, in the county of Glamorgan, with gas, electricity, oil or other illuminating power; to acquire, construct, maintain and work the necessary plant, engines, machinery and appliances, for making, generating, storing, accumulating and distributing gas and electricity; and to manufacture, sell and deal in lamps, brackets, globes, burners, meters, galvanometers, ammeters, voltmeters, carbons, cutouts, switches, motors, batteries, &c.

ELECTRIC LAMP COMPANY (LIMITED).—This Company was registered on the 28th ult., with a capital of £4,000, in £1 shares. The objects are to carry on the business of an electric light company in all its branches, electricians, electrical and mechanical engineers, suppliers of electricity, and manufacturers of and dealers in all apparatus and things required for or capable of being used in connection with the generation, distribution, supply, accumulation, and employment of electricity.

HOLLOWAY ELECTRICITY SUPPLY COMPANY (LIMITED).—This Company was registered on the 30th ult., with a capital of £2,000, in £10 shares. The objects are to purchase, take on lease or otherwise acquire and to establish and maintain central and other stations, from which electricity may be supplied; to carry on, in the parish of Islington, or elsewhere, the trade or business of electric lighting in all its branches, to obtain any Act of Parliament or any Provisional Order or licence of the

Digitized by Google

Board of Trade or of any municipal or local authority for enabling the Company to carry any of its objects into effect, and to manufacture, deal in, or let out on hire instruments, appliances, plant, or apparatus for producing, storing, distributing, supplying, using, regulating, or measuring electricity. The subscribers (with one share each) are Sidney Sharp, 34, Victoria-street, S.W., engineer; J. M. Kent, 34, Victoria-street, S.W., engineer; E. J. Piper, 4, Tollington-road, Holloway; P. W. Rands, 5, Boswell-road, Croydon; C. P. Heap, 60, Waldegrave Park, Strawberry-hill, engineer; H. A. Folkard, 9, Ormiston-road, Uxbridge-road, W.; G. W. Harrow, 4, Lonsdale-square, Barnsbury, N. The Directors may purchase or otherwise acquire and undertake, upon such terms and conditions as they think fit, the business or businesses of a central electric lighting station and electrical engineers and contractors, now carried on by Messrs. Sharp and Kent, at Tollington-road and elsewhere in the parish of St. Mary, Islington. The number of Directors is to be not less than three nor more than seven, the first to be elected by the signatories. Qualification, £500; remuneration, as the Company in general meeting determine.

HOPE-JONES ELECTRIC ORGAN COMPANY (LIMITED).—This Company was registered on the 1st inst, with a capital of £25,000, divided into 1,200 preference and 1,300 ordinary shares of £10 each. The objects are to acquire certain letters patent, inventions, businesses, and premises, set forth in an agreement dated June 30, 1892, between Robert Hope-Jones, electrician and engineer, of 55 and 57, Argyle-street, Birkenhead, of the one part, and Frederick B. Townsend (on behalf of this Company) of the other part; to apply electric and pneumatic apparatus to organs and other musical instruments; to carry on business as builders and manufacturers of organs and other musical instruments, and as electricians; and to manufacture, sell, and deal in electric, pneumatic, and other apparatus. The first Directors are:—Thomas Threlfall, G. A. W. Beard, William Creser, W. D. Hall, and Robert Hope-Jones.

RAILWAY ELECTRIC READING LAMP COMPANY (LIMITED).—This Company was registered on the 4th inst., with a capital of £100,000, divided into 16,000 ordinary and 4,000 deferred shares of £5 each. The objects are to purchase from the Railway Automatic Electric Light Syndicate (Limited) the patents for the United Kingdom for electric reading lamps, granted to Dixon H. Davies and John M. Tourtel, which are referred to in the draft of an agreement which it is intended to enter into between the said Syndicate of the first part, John M. Tourtel and Dixon H. Davies of the second part, and the Company of the third part; to take over the benefits and obligations of an agreement dated May 27, 1892, between the Metropolitan District Railway Company of the one part, and the Railway Automatic Electric Light Syndicate (Limited) of the other part, and to enter into an agreement with the Metropolitan District Railway Company, by which the Company will be authorised to instal and work automatic electric reading lamps in carriages of the said Railway Company; and to manufacture, construct, use, sell, let, or otherwise deal with electric lamps, for use in railway and other carriages, steamships, reading rooms, tramcars, &c. The subscribers (with one share each) are Benjamin H. van Tromp, Emile Garcke, Edmund Etlinger, W. H. Fox, J. Cecil Bull, John M. Tourtel, and Frederick C. Cocking. The first Directors are Edmund Etlinger, John H. Kincaid, Charles E. Spagnoletti, and Benjamin H. van Tromp, Qualification, 50 shares; remuneration, £800, and in each year in which a dividend of £7 per cent. per annum has been paid, £5 per cent. of the excess, the said remuneration to be divided as they themselves determine.

MISCELLANEOUS. — Chemists' Association (Limited), wholesale chemists; capital, £50,000, in £1 shares.——Hotel Belgravia (Limited), hotel proprietors and producers and suppliers of electricity; capital, £60,000, in £5 shares.——Thomas Piggott and Co. (Limited), electrical and mechanical engineers; capital, £90,000, in £10 shares.

BLOCKLEY ELECTRIC LIGHTING AND MANUFACTURING COMPANY (LIMITED).—The annual return of this Company, made up to June 13th, was filed on the following day. Out of a capital of £20,000 in £5 shares, 461 ordinary and 67 £5 per cent. preference shares have been taken up, and the full amount called, resulting in the payment of £2,640.

EVERED AND CO. (LIMITED).—The annual return of this Company, made up to April 14th, was filed on June 3. At the time of making-up 16,496 shares had been taken up, and upon 6,744 of these the full amount had been called, and upon the remaining 9,752 shares a call of £7 per share had been made, resulting in the total payment of £135,704.

GREENWOOD AND BATLEY (LIMITED).—The annual return of this Company, made up to June 24th, was filed on the 30th. At the time of making up, 11,066 preference and 18,052 ordinary shares had been taken up, of which 2,666 preference and 4,666 ordinary shares had been issued as part payment of the purchase consideration. Upon 9,600 preference and 16,800 ordinary shares (which numbers include the shares issued as fully paid), the full amount had been called, while upon the remaining 1,466 preference and 1,252 ordinary shares a call of £3 per share had been made, resulting in the payment of £198,834.

REGENT PORTABLE ELECTRIC LAMP AND LIGHTING COMPANY (LIMITED).—As the above-named Company had filed no returns since its incorporation, it has been dissolved by notice in the *London Gazette*, dated June 21, 1892. The Company was registered on August 27, 1886, with a capital of £85,000, in £5 shares, to acquire the exclusive licence for manufacturing and selling the Regent Primary Battery, in accordance with the said licence, for all purposes in connection with the electric lighting in Great Britain and Ireland.

WATER PRIMARY BATTERY COMPANY (LIMITED).—In spite of repeated notices the above-named Company has not complied with the regulations, and a notice has just been filed that the Company has been dissolved. The Company was registered on December 23, 1886, with a capital of £100,000, in £5 shares, to enter into an agreement with Paul R. de F. D'Humy for the acquisition of certain patents and to carry on the business of manufacturers of and dealers in machines, chemicals, and appliances for the production, storage, and transmission of electricity. On August 6, 1887, 3,000 shares had been taken up, of which all had been issued as fully paid, and no return has been filed since that date.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended July 3rd were £763, as against £719 for the corresponding period of last year, being an increase of £44. The total receipts to date, from January 1st last amount to £21,210, against £19,917 in the corresponding period of 1891, being an increase of £1,293.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of June were £3,400, as compared with £3,509 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The receipts of this Company for the month of June amounted to £1,966, as compared with £1,882 in the corresponding period of last year, an increase of £84.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the month of June amounted to £52,173, against £52,341 in the corresponding period of 1891, being a decrease of £168.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of June amounted to £41,738, and to £39,749 in the corresponding period of last year, an increase of £1,989.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).—Subject to audit, the shareholders will be recommended at the forthcoming general meeting to declare a dividend on the "A" shares of the Company, of 5s. 8¾d. per share on the 89,261 ordinary shares, £3 paid; of 9s. 6¼d. per share on the 5,000 £5 fully-paid shares allotted to the Edison Electric Light Company (Limited); and of 8s. 10⅞d. per share on the 12,139 £5 fully-paid shares allotted to the Swan United Electric Light Company (Limited), free of income tax, being, with the interim dividend paid on February 22, 1892, 7 per cent. in respect of the year ended June 30, 1892, 7 per cent. in payment of arrears of cumulative preferential dividend for the year ended June 30, 1887, and of 4 per cent. in respect of the year ended June 30, 1888; all to be distributed in accordance with the provisions of Clause 87 of the "Articles of Association."

ELMORE'S PATENT COPPER DEPOSITING COMPANY (LIMITED).—Application has been made to the Stock Exchange Committee to allow the additional shares of this Company to be quoted in the official list.

ENGINEERING EXCHANGE (LIMITED).—A prospectus of this undertaking has been issued, which is incorporated with a capital of £10,000 in £10 shares, payable: £1 on application, £1 on allotment, £1 one month after allotment, and the balance at the discretion of the Directors. In the twenty names forming the committee of the Exchange are included the following: Mr. Charles Churchill, Mr. J. Alfred Fisher, Mr. F. H. Nalder, Mr. James Paxman, Mr. F. L. Rawson, and Mr. A. H. Tyler. The registered offices ar situate at 33, Old Broad-street, E.C., and the exchange rooms at Billiter House, 22, Billiter-street, E.C. The secretary is Mr. A. T. Salisbury-Jones.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this Company for June, 1892, amounted to £24,000; and from January 1st to June 30th to £128,800. In the corresponding months of 1891 and 1890 the amounts were £141,400 and £130,400 respectively.

HOBART TRAMWAY COMPANY (LIMITED).—The first ordinary general meeting of the shareholders of this Company was held at the offices on Thursday, last week, under the presidency of Sir Edward Braddon, K.C.M.G. The Chairman said it had been decided to use overhead electrical power, which they believed to be not only the best but the cheapest; and terms of a very favourable character had been made with the eminent firm of Messrs. Siemens Bros. and Co. (Limited), to whom the work of equipment and carrying on the line during the first twelve months had been entrusted. He defended the Directors' estimate of traffic and reminded the shareholders that the Company, besides the revenue they will acquire by passenger traffic, will also earn money from the carriage of goods and parcels; and further, that the electrical plant to be put up may very probably prove revenue earning, as the Company will be in a position to supply electricity for public or private service to the citizens of Hobart.

INDIA-RUBBER ESTATES COMPANY (LIMITED) (IN LIQUIDATION).—The creditors of this Company met on Thursday, last week, at Carey-street, Lincoln's-Inn-fields, before Mr. Warley, assistant receiver, to consider the present position of affairs. In the course of the meeting, the Chairman announced that a total sum of £4,620 had been realised from the assets up to the present time. The Official Receiver had a sum of £595 in hand, and anticipated being able to recover a further sum of about £200. A dividend of 15s. in the pound had already been paid to the creditors, and a further dividend of 2s. 6d. or 3s. in the pound would be declared. The concession was in the hands of the Liberian Concessions Company, who had a claim of £631 15s. against the India-Rubber Estates Company; but negotiations were pending under which it was anticipated that the Liberian Concession Company would, in exchange for the Company's interests in the concession, withdraw their claim, pay a sum to the Official Receiver for the benefit of the creditors, and allot 5,000 shares in their own company to the shareholders in exchange for the shares in the India-Rubber Estates Company now held by such shareholders. The meeting was adjourned for a week

Digitized by Google

to enable the negotiations with the Liberian Concessions Company (Limited, to be carried through with a view to an amicable settlement.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).—Notice is given in our advertisement columns that the transfer books of this Company will be closed from the 4th inst. to the 12th inst., both days inclusive, preparatory to the payment of an ad interim dividend of 12s. per share to all shareholders on the register on the 4th inst.

MANITOBA ELECTRIC AND GAS LIGHT COMPANY.—Messrs. Robert A. MacLean and Co. will, on and after to-day, pay the half-year's interest due on that date on the Six per Cent. First Mortgage Debentures of this Company.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The receipts of this Company for the fortnight ended June 30, 1892, amounted to £2,204, as compared with £2,265 in the corresponding period of last year, a decrease of £61.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended July 1, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,701.

WOODHOUSE AND RAWSON UNITED (LIMITED).—The Stock Exchange Committee have been applied to to appoint a special settling day in the ordinary and preference shares of this Company.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 739.—Vol. XXIX. FRIDAY, JULY 15, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

Litigation about glow-lamp patents has ceased to interest most of our readers, and we need not therefore give much attention to the recent decision in the American Courts. The United States Electric Lighting Company proceeded against the Edison Lamp Company for infringement of Weston's "flashing" patent. It was proved that the exhibition of a number of lamps by Sawyer and Man containing flashed carbons between March, 1878, and May, 1879, was a "practical and public use," and the validity of their patent was therefore upheld. This was some time before Edison had turned his attention to carbon. The English patent for flashing, known as the "Cheeseborough" patent, was for this invention, Cheeseborough being the name of the patent agent employed by Sawyer and Man. Because the Edison and Swan Company fought over this patent in 1888, many people thought, and still think, that "flashing" was invented by Edison. A few others still believe that Cheeseborough was a forgotten pioneer. The "flashing" patent expires on November 28 of the present year. The Edison carbon filament patent expires on November 10 next year.

We have already recorded the result of the action of the Electrical Trades Section of the London Chamber of Commerce with regard to the overhead wire rules of the London County Council. After all the trouble about the Board of Trade rules which touch on a closely allied matter, the assistance of that body was very welcome; and Major Flood Page's assurance that the Board of Trade officials are most willing to try and alter anything that is really restrictive to trade is very satisfactory. It is, of course, easier to contemplate alterations in somebody else's rules than in one's own; but we look forward to the time when, the interference of the London County Council having become unbearable, all these matters will be efficiently carried out by a competent and well-equipped Electrical Department of the Board of Trade.

The application for space in the Electrical Section of the Chicago Exhibition by English firms is not surprisingly small, but the representation of English electrical engineering is ridiculous. Only 5,000 square feet have been taken up out of the 20,000 which have been allotted. More than one-fifth of this will be occupied by Elwell-Parker machinery, while the only other specimens of dynamo machinery which are promised are those of Parsons and Ferranti. No better types could perhaps be selected to attract attention, on account of their strong originality. The makers of the biggest dynamo and of the fastest-running one ought not to be absent from such a show; and we hope that they will not be disappointed in their venture. One other substantial firm is exhibiting, and Mr. Binswanger knows well what he is doing; but after these, a deluge of electrical ventilators and homacoustic speaking-tubes, and the like. After reading Mr. Preece's list, which will be found in another column, we are almost inclined to think that there may be something in his idea of a syndicate and a comprehensive show to cover say another 5,000 feet with some really first-rate selections; but it is not improbable that many dynamo makers agree with the steam-engine makers as to the policy of exhibiting at all.

At the last meeting of the Commission of Sewers the engineer asked for authority to get a new plan of the City. The present one was prepared about twenty years ago, and the copies are now exhausted. It was suggested some years since that whenever electric mains were laid, an accurate plan of their route should be made. Supply companies use the Ordnance maps as a rule, but the position of the conductors can be only approximately given on them, on account of their small scale and the numerous alterations which have been made since the date of the survey. The London County Council has missed a grand opportunity for doing something very useful. It might have provided a staff of surveyors to note the position of all pipes that were exposed whenever the streets were opened, and of all wires and pipes that have been laid, and conduits that have been constructed. We have often stopped to look into excavations during the laying of electric mains, and have marvelled at the network of gas and water pipes; but we should be glad to know if sketches are regularly made of the bowels of the streets either by the contractors or by the local authorities.

The discussion of the dimensions of physical quantities can, perhaps, only be interesting from a purely scientific point of view. Its value in theoretical work has, however, been frequently shown, notably, for instance, in connection with the electromagnetic theory of light; and we cannot share the hopeless view, expressed in another column, that dimensions are useless, and should be suppressed altogether. The article on this subject, which we publish to-day, is, nevertheless, interesting, because it points out many of the difficulties which

Digitized by Google

must be surmounted before a clear and complete interpretation of dimensional equations can be given. Our correspondent, "W. M. M.," thinks that this is practically impossible, since, if otherwise, it is remarkable that it has not yet been done. He also advances the disputable opinion that "these physical equations" are to be regarded as a "hindrance in education, since they are one more step in the direction of making our symbols do our thinking for us; and of this there is already too much in mathematics." Whether this is or is not an argument against the use of these equations for educational purposes, it is an admission of their usefulness in other directions.

The more we can utilise symbols as thinking machines the better. The processes used in any mathematical research are analogous with those of a slide rule. Data are supplied to start with, certain recognised operations are gone through, and a result is arrived at, which is a necessary consequence of the data given, but which would have been difficult, if not impossible, to think out. In the same way the study of dimensional equations sometimes yields results which could not have been arrived at so readily by other methods.

The very interesting correspondence which has been elicited by our remarks on carbon brushes for dynamos has touched only on the practical side of the question, but even here there are some discrepancies. Mr. Sayers, using brush-holders intended for copper brushes, can only give about 0·624 square inch for 60 amperes, say, 100 amperes per square inch, and is sometimes compelled to use 200 amperes per square inch. Mr. Dallas gives figures which work out to 75 amperes per square inch, Mr. Housman recommends no more than 40 or 50 amperes, and Mr. N. G. Thompson only 30 amperes. The theory of the carbon brush we leave for a future occasion.

In our "Legal Intelligence" columns we publish the summaries of arguments which were handed in by both plaintiff and defendant in the Lane Fox appeal. It is very unusual, after full *viva-voce* arguments, to allow any such document to be provided; but it was done at the suggestion of Lord Justice Lopes. The *Glasgow Herald* notices this as an interesting precedent, and says that this concession, which involves a return to an early practice in the history of English pleading, is not only a great assistance to the Bench, but an advantage to litigants, who are thus enabled to avoid the risk of errors creeping into the Judges' notes, and it is believed that in similar cases it will be granted to suitors as a matter of course.

The nature of the demand for domestic electric lighting may be judged from the meters in use. We learn that, during last year, Messrs. Ferranti and Co. found that 25-ampere meters were chiefly asked for; but now the 15-ampere size is most popular. The demand for 5-ampere meters is still increasing, which shows that small houses, fitted with only 14 or 15 lamps, are taking up the supply. This increase of small customers is very satisfactory, and it is probable that they will use their lamps with greater economy than is general in large establishments.

We understand that the legalisation of the ampere, volt, and ohm has been deferred, in order that another attempt may be made to arrive at an international arrangement With this in view, Prof. von Helmholtz is expected to attend the meeting of the British Association, and it is hoped that Profs. Mascart and Rowland will also be present.

Electric Tramway in Normandy.—The Chamber of Commerce of Honfleur have been asked to consider the construction of an electrical tramway between Honfleur and Trouville.

Chiswick.—The Chiswick Local Board give notice of their intention to transfer to Messrs. Bourne and Grant for a period of 21 years the powers granted to them under their Electric Lighting Order.

"Sounder" v. "Morse."—In the new chief office of the Posts and Telegraphs in Brussels telegraphic receivers of the "Sounder" type are being installed in place of the "Morse" type, which have been in use during the last four years.

Cable Interruptions.—

Mossamedes, Cape Town	June 26, 1892.
Sierra Leone, Accra	July 14, 1892.

By these interruptions all telegraphic communication with the West Coast of Africa between Accra and Mossamedes is cut off.

Enamel Insulation.—Resistances for motors, &c., are being made in Chicago with wire buried in enamel, making a fireproof and compact arrangement. They will probably take longer to warm up, and will not be able to get rid of their heat as readily as wire coils.

Barnsley.—After considering two electric lighting schemes, the Lighting Committee of the Barnsley Town Council have reported in favour of a continuous-current scheme, and recommend that application be made to the Local Government Board for sanction to borrow £18,382.

Copper.—In future, says the *Financial Times*, the Anaconda Company, instead of shipping its matte to Europe, will have it refined at Baltimore. As one practical effect of this change, the Americans will send us more fine copper than ever, and have proportionately greater control over our market.

The Cable Fleet.—Owing to the death of Captain Fawcus, of the Eastern Extension, Australasian and China Telegraph Company's service, Captain Madge has been transferred to the ss. "Sherard Osborn," from the ss. "Recorder," to which latter vessel Captain Brereton, first officer of the "Sherard Osborn," has been appointed.

Bruce's Signalling Balloon.—Experiments were made last week, at the Stamford Bridge Grounds, with a modified and improved sigualling balloon. The balloon, which is 18ft. in diameter, is made of varnished cambric. Glow-lamps are used either inside or outside, current being supplied by a twin wire. The improvements consist in reduction of weight in the fittings as well as in the cable.

Breslau.—We learn that the work of construction of the electric tramway in Breslau will be proceeded with very soon, and the line is to come into operation next summer. It is proposed to have four lines, with through car communication. The total length of rails will be 28 kilometres—a length to which no existing Continental electric tramway has attained as yet. The line will be worked on the overhead conductor system.

Bradford Tramways.—The Electric Lighting Committee of the Bradford Corporation have offered to supply the Tramways Committee with power for the Wakefield-road trams at 2½d. per unit, on condition that at least 120,000 units are used per year. This will give the Tram Committee a working basis upon which to advertise for tenders for the new line. The

Digitized by Google

Committee are said to have under consideration the advisability of adopting the use of cheap gas power instead of steam.

Gas Mains and Steam Rollers.—From some correspondence which has appeared in a recent number of the *Gas World* we learn that considerable damage has been done to the gas mains in the streets of Cork by a steam roller. Several manufacturing and business firms were without a supply of gas, and one firm had four gas engines and 70 men standing idle. Fortunately a water pipe was also fractured, and the water escaped into the gas pipes, thus preventing, we are told, the consequences from being more serious.

Pacific Cable Survey.—The United States survey steamer "Thetis" arrived at Honolulu on May 20th from Hilo, where she ended the survey for the proposed cable between San Francisco and the Hawaiian Islands. The course to Hilo comprised 2,060 miles as surveyed by the "Thetis," with 300 soundings, against the survey of the "Albatross" of 2,150 miles, and 250 soundings. The soundings were made at intervals of ten, two, and sometimes one mile apart. The deepest was 3,228 fathoms, about 245 miles north-east of Hilo, and the shoalest was 976 fathoms, at a point about 350 miles from Point Conception.

Charlottenburg.—Messrs. Siemens and Halske have, according to some of the Berlin papers, made application for a concession for the construction of an electric tramway from the Spandauer Bock on the Spandauer Chaussee as far as the municipal boundary of Charlottenburg. The concession of the present horse tramway which works the traffic in the above districts expires on the 1st July, 1895. As the existing tramway, which unites the southern portion of Berlin with Charlottenburg, hardly meets the requirements of the day, Messrs. Siemens and Halske propose to extend the electric road from the Charlottenburg boundary on to Berlin.

British Association.—The sixty-second annual meeting of the British Association will commence on Wednesday, August 3, 1892, under the presidency of Sir Archibald Geikie. The general secretaries are Captain Sir Douglas Galton and Mr. A. G. Vernon Harcourt. The assistant general secretary is G. Griffith, Esq., and the local secretaries for the meeting are: Professor G. F. Armstrong, Messrs. John Harrison and F. Grant Ogilvie. Local treasurer for the meeting at Edinburgh, Adam Gillies Smith, Esq. The presidents of sections are:—Section A., Mathematical and Physical Science, Prof. Arthur Schuster; B., Chemistry and Mineralogy, Prof. Herbert McLeod; C., Geology, Prof. Charles Lapworth; D., Biology, Prof. W. Rutherford; E., Geography, Prof. James Geikie; F., Economic Science and Statistics, the Hon. Sir C. W. Fremantle; G., Mechanical Science, Prof. W. C. Unwin; H., Anthropology, Prof. Alexander Macalister.

Graphite and Graphitite.—Graphite plays an important part in the manufacture of arc-light carbons, and has in the process to be first of all finely powdered. According to some researches of W. Luzi (*Deutsch. Chem. Gesellschaft*, Vol. XXIV.), certain kinds of graphite, which he proposes to call *graphitite*, may be very easily reduced to powder by chemical means. It has been known for some time that graphite boiled in certain reagents, and then washed and dried, swelled in a most extraordinary fashion when baked. These reagents were concentrated sulphuric acid and a mixture of concentrated sulphuric and nitric acid. W. Luzi finds that fuming nitric acid is also a reagent. The graphite which exhibits this peculiarity of swelling comes from the following sources:—Ticonderoga, Pfafferreuth, Ceylon, Buckingham (Canada), Argenteuil (Canada), Massachusetts, Amity (N.Y.), Greenville (Ont.). The so-called graphitite comes from Passa (Siberia), New Mexico, Burkhardtswald (Saxony), Idar, Fichuelgebirge, Diedelkopf (Tyrol), Levigliani (Italy).

Exports of Telegraphic Apparatus.—The Board of Trade returns for June show a very small export of telegraphic wire and of apparatus connected therewith, the total value of our exports for the first half of the current year falling below the figures for the corresponding half years of 1890 and 1891. In April last our exports were valued at over £400,0 0, but this amount has not been sufficient to offset the falling-off in the other months of the half-year. The following is a monthly statement of exports in comparison with the corresponding periods of the two previous years:—

	1890. £	1891. £	1892. £
January	71,686	238,223	46,246
February	201,594	22,306	31,006
March	51,390	392,552	18,827
April	187,733	59,226	447,883
May	57,081	51.238	107,696
June	152,228	220,985	24,177
	721,712	984,530	675,835

Iron for Electrical Purposes.—Many text-books say a good deal about the permeability of iron. This is a matter of comparatively small importance; what we really want to know, says *Industries*, relates to magnetic hysteresis. The universal instruction at present is, "Buy soft Swedish charcoal iron." This is good, but not cheap. Makers want an iron which is cheap and which is always good and can be depended upon. It should have high specific resistance. This is a point which, we believe, is always neglected. It may be incompatible with small hysteresis. If not, however, it admits of the use of thicker iron, and this is cheaper and more easy to work. Another point, generally overlooked, is that the iron must not harden easily. Whether there are differences in this or not we do not know. A very little rough handling in the works will double the hysteresis loss in an armature. If a particular grade of iron has slightly greater hysteresis than another, but will stand straining without hardening, it may be much better in practice than a quality which is better when perfectly annealed.

The Central Stations of Europe.—The following statistics are based on a table published in the *Bulletin de la Société Belge d'Electriciens*. According to this authority there are 21 central stations in Europe from which distribution on the plain two-wire system takes place; the two largest being those at Lyons (16,400 8-c.p. lamps) and at Bilbao (8,000). There are no less than 36 three-wire central stations from which the equivalent of more than 600,000 8-c.p. lamps can be supplied. There are only three examples of the five-wire system, namely in Paris (Place Clichy), Königsberg and Trient, but their lamp capacity amounts to close on 70,000. Some 23 central stations employ accumulators in parallel with the dynamos, and five have adopted the accumulator sub-station system. Four stations employ continuous-current transformers, and 55 employ alternate-current transformers, the latter having a total 8-c.p. lamp capacity of something like three quarters of a million. A single station, that at Heilbronn, is worked on the "rotary current" system. Some 39 stations, mostly small ones, are not included in any of the above categories.

Water Level Indicator.—Many clumsy and a few ingenious electrical devices have been tried for measuring the depth of water at a distance. Prof. F. J. Smith describes the following very interesting and apparently practical method in yesterday's *Nature*:—

"About two years ago I wished to know from time to time the rate at which a river was rising after a fall of rain. The river was at a considerable distance from the spot where its height was to be known. By means of the combination of two organ pipes, and a telephonic circuit, described in the following lines, I have been able to make the required measurement within rather close limits. At the river station, an organ pipe was fixed vertically in an inverted position, so that the water in the river acted as a stopper to the pipe, and the rise or fall of the water determined the note it gave, when blown by a small bellows driven by a very small water wheel. A microphone was attached to the upper end of the organ pipe; this was in circuit with a wire leading to a town station at some distance; at the town station there was an exactly similar organ pipe, which could be lowered into a vessel full of water while it was sounding. By means of the telephone the note given by the pipe at the river was clearly heard at the town station; then the organ pipe at this station was lowered or raised by hand until it gave the same note. The lengths of the organ pipes under water at the two stations were then equal, so that the height of the water in the distant river was known. The determination can be made in less than a minute by any one who can recognise the agreement of two similar notes. The arrangement when first tested was so placed that the height of water at two places near together might be easily compared. I found that a lad with an average ear for musical sounds was able to get the two heights to agree within one-eighth of an inch of each other, while a person with an educated ear adjusted the instrument immediately to almost exact agreement. The total height to be measured was 17 inches.

Digitized by Google

A difference of temperature at the two stations would make a small difference in the observed heights. For example, taking a note caused by 250 vibrations per second, a difference of 10°C. between the temperatures of the two stations (one not likely to occur) would make a difference of about 0·02 foot in the height, a quantity of no moment in such a class of measurements. The organ pipes were of square section, and made of metal to resist the action of the water."

The Utilisation of Central Station Exhaust Steam.—The American central-station engineer in quest for a dividend has lately lighted upon a source of profit which, unfortunately, is not equally available to his English *confrère*, namely, the utilisation of the exhaust for steam-heating purposes. At Springfield, Ill., the exhausts of the engines are connected to the mains of the steam-heating plant, which are 8 inches in diameter and which shortly after leaving the station branch into smaller mains, 6 inches in diameter. This exhaust steam is being furnished for heating to about 16 business blocks, and not the least difficulty has been found in securing in the immediate vicinity of the station all the business that can possibly be taken care of. Ordinary radiators are employed, and something over 2,000,000 cubic feet of air space is now being heated, and this will be increased to over 3,000,000. The amount of power of exhaust steam at present in service at a pressure of about 5lbs. is 200 horse-power. Contracts are now based upon a charge of 20 cents per foot of direct radiation per year, or 25 cents on indirect radiation. The use of this system, while yielding a most generous profit to the station, is also cheaper for the consumer; and from the fact of steam being on day and night it has been demonstrated that 25 per cent. less heating surface is required than where the heating is done by boilers in the buildings; in many cases this percentage of radiating surface has been taken out on account of the heat being greater than required. An average estimate for the amount of heating surface required is one square foot of radiation to 50 cubic feet of air. At the station an automatic device is provided to prevent the pressure exceeding 5lbs., and the 5lbs. back pressure on the engines is compensated for by an additional 5lbs. pressure on the boilers. The additional amount of fuel required during the time of heating does not exceed 5 per cent.

Oxidation of Nitrogen by Electric Sparks.—A Paper upon the oxidation of nitrogen by means of electric sparks is contributed, by Dr. V. Lepel, to the current number of the *Annalen der Physik und Chemie*. It is well known that small quantities of nitric and nitrous acids and their ammonium salts are produced during the passage of high-tension electrical discharges through moist air. Dr. V. Lepel's experiments have been conducted with the view of obtaining more precise information concerning the nature of the chemical reactions which occur, and the experimental conditions most favourable for increasing the amount of combination. The first action of the spark discharge appears to be the production of nitric oxide, which is immediately converted by the oxygen present into nitrogen peroxide. The latter then reacts with the aqueous vapour present, forming nitric acid and liberating nitric oxide in accordance with the well-known equation $3NO_2 + H_2O = 2HNO_3 + NO$. It has been found, however, that the passage of sparks through the gaseous oxides of nitrogen first formed, results in their decomposition again into their elementary constituents. Hence it is that, in a closed space, a limit is soon reached beyond which there is no further increase in the amount of nitric acid. For this reason the yield of nitric acid has hitherto been very small. Dr. V. Lepel has made experiments, therefore, with a slowly moving atmosphere, and under different conditions of pressure, and with various types of spark discharge, with the result that he has already increased the amount of combination to 10 per cent. of the total amount of air employed. Of particular interest are his remarks concerning the probable effect of the high-voltage discharges of which we have lately heard so much. He considers it not improbable that by their aid a new mode of producing nitric acid from the atmospheric gases on the large scale may be introduced, rendering us altogether independent of the natural nitrates as a source of nitric acid.

The Periyar Irrigation Project in Madras.—The Government of Madras, says Prof. Alfred Chatterton in the *Indian Engineer*, are engaged in diverting the water of the Periyar river, which rises in the Western Ghauts and flows into the Arabian Sea near Cochin, so as to make it available for irrigation purposes near the town of Madura. The works, which have been designed by and are being carried out under the superintendence of Colonel Pennycuick, R.E., consist in the construction of a masonry dam 155 feet high, whereby the waters of the river will be dammed back to form a lake having a superficial area of over 10 square miles, and containing at the level of the escapes 13,299 million cubic feet of water. The water thus stored will be taken through the watershed ridge by a cutting and tunnel. The quantity of water stored which it will be possible to draw off amounts to 6,815 million cubic feet, but as the water-shed is situated in a region where the rainfall is at least 100 inches per annum, and as the area amounts to about 300 square miles, and as the rainfall is distributed over more than eight months of the year from April to December, it will be possible to draw off from the lake a quantity of water equal to 1,500 cubic feet per second from the middle of April to the middle of December; and as at the end of that time the lake will still be full, it will contain enough water to deliver 750 cubic feet per second for three months, and the drainage from the occasional showers which fall in the earlier months of the year will be more than sufficient to give the extra month's supply which is required. The tunnel through the ridge will be about a mile long, and will deliver the water on the eastern side of the Ghauts at an elevation of about 2,850 feet above the sea. The hills rise very abruptly on this side, so that in about a mile the water will fall some 1,300 feet. It is this fall of 1,300 feet immediately after the exit of the water from the tunnel that it is proposed to utilise for power purposes. It is situated near Kuruvanuth, a small village at the head of the Cumbum valley, some 70 miles from Ammanayakanur, the nearest railway station on the South Indian Railway, which is 320 miles from Madras.

Telephone Enterprise in Belgium.—Mr. Conyngham Greene, of the British Legation in Brussels, has lately written a report on the history and progress of telephone enterprise in Belgium, from which it appears that up to 1883 the telephone service in that country was in the hands of private companies, and the uncertain character of the concessions granted by the State checked the free expansion of private enterprise. Between 1880 and 1883 three separate telephone systems were in operation in Brussels, but, owing to competition and the refusal of the companies which worked the lines to grant mutual subscriptions over the lines of their rivals, no great success was obtained by any of them. In 1883 the State Department of Posts and Telegraphs took the initiative in organising and developing the telephone system of the country. A law was then passed authorising the Government to undertake themselves, or to concede on fixed conditions to others, the establishment and development of telephone lines. In a few months the Bell Telephone Company bought up the two rival companies of Brussels and secured a concession not only for the capital itself, but also for Ghent, Antwerp, Verviers, and Charleroi. The Company started with a paid-up capital of £105,400, of which more than two-thirds was devoted to buying up the rival plant and apparatus and replacing that which was worn out and inefficient. The existing wires were replaced by phosphor-bronze wires on the Montefiore system. Owing to the superior capability of this wire for bearing a strain, it was found possible to diminish the number of supports, and thus to get rid of much useless material. Moreover, the expense of repairing the wires was materially reduced, as breakages were of very rare occurrence, and the interruption of the service proportionally unusual. By way of dividend the Company distributed in 1889 among its shareholders £10,750, and £15,181 in the following year, while the number of subscribers rose from 4,051 on December 31, 1888, to 4,726 in 1892. The State has also laid and worked lines of its own to the less important centres which were somewhat neglected by the companies. A system of receiving and transmitting telegrams by telephone to subscribers has been introduced and has proved a great success. The repurchase of all the telephone concessions by the State will probably take effect from January 1st next, when a further large extension of the telephone system will take place. It appears, however, that in regard to Press messages between Paris and Brussels the telephone has wholly supplanted the telegraph.

ELECTROMAGNETIC THEORY.—XXXII.

BY OLIVER HEAVISIDE.

(*Continued from page 189.*)

§ 148. As we see from the preceding that the propagation of electromagnetic disturbances through a non-conductor can be imitated in an incompressible solid, possessing the usual distortional rigidity, let us next introduce electric conductivity on the one hand, and examine what changes are needed in the analogies of §§ 146, 147 to keep them working, if it be possible. Since there is waste of energy associated with the conduction current, it is clear that some sort of frictional forces requires to be introduced into the elastic solid.

First try distortional friction. The equation of motion of an incompressible viscous solid is

$$\mathbf{f}_1 = [\rho p^2 - (n_0 + n_1 p)\nabla^2]\,\mathbf{G}, \quad . \quad . \quad . \quad (329)$$

where $\mathbf{f}_1$ is the impressed force per unit volume, $\mathbf{G}$ the displacement, ρ the density, n_0 the rigidity, and n_1 the associated frictionality. Also, p stands for d/dt, for practical convenience in the operations, whether direct or inverse. Thus, $p^{-1}\mathbf{q}$ or $\mathbf{q}/p$ means the time-integral of $\mathbf{q}$, which would in the ordinary notation of the integral calculus be expressed by $\int_0^t \mathbf{q}\,dt$, a notation which is not convenient for manipulative purposes in investigations of this class. We may derive (329) from (324) by changing n to $n_0 + n_1 p$; or by (306), (313).

Now the circuital equations of $\mathbf{E}$ and $\mathbf{H}$ in a conducting dielectric (homogeneous, isotropic, stationary), are

$$\text{curl}\,(\mathbf{H} - \mathbf{h}) = (k + cp)\,\mathbf{E}, \qquad \text{curl}\,(\mathbf{e} - \mathbf{E}) = \mu p \mathbf{H}, \quad . \quad (330)$$

comparing which with (323) we see that the effect of introducing conductivity is to change cp to $k + cp$, so that the equation of $\mathbf{H}$ is got by making this change in (325), giving

$$\mathbf{f} = \left(\mu p - \frac{\nabla^2}{k + cp}\right)\mathbf{H} = \left(\mu p^2 - \frac{p\nabla^2}{k + cp}\right)\mathbf{Z}, \quad . \quad . \quad (331)$$

where $\mathbf{Z} = \mathbf{H}/p$. But on comparing this equation with (329), we see that the viscosity in the one case and the conductivity in the other enter into the equations in different ways. We can only produce a proper correspondence when the coefficients of ∇^2 are equal; or, in another form, when the operators $p(k + cp)^{-1}$ and $(n_0 + n_1 p)$ are equivalent in effect. This is not generally possible. But there are two extreme cases of agreement. One we know already, viz., when there is no conductivity and no viscosity, as in § 146. The other is when there is no permittivity and no rigidity, which is sufficiently important to be separately considered.

§ 149. This is the extreme case of a pure conductor, or a conductor which cannot support elastic displacement. It dissipates energy, but does not store it electrically; though, on the other hand, its magnetic storage capacity is retained. It is compared with an incompressible viscous solid with the rigidity abolished; that is to say, with an incompressible viscous liquid. Put $c = 0$ in (331), and we have the equation

$$\mathbf{f} = (\mu p - k^{-1}\nabla^2)\mathbf{H}; \quad . \quad . \quad . \quad . \quad (332)$$

and putting $n_0 = 0$ in (329), with $\mathbf{q}$ the velocity substituted for $p\mathbf{G}$, gives us the equation

$$\mathbf{f}_1 = (\rho p - n_1\nabla^2)\mathbf{q} \quad . \quad . \quad . \quad . \quad . \quad (333)$$

in the liquid. These admit of immediate comparison. Observe, however, the curious fact that whereas in § 146 the permittivity was the reciprocal of the rigidity, so that the vanishing of one means the infinitude of the other, yet now both the permittivity and the rigidity vanish together, as if they were equivalent. This emphasises the incompatibility of (329), (331). Our present analogy must stand by itself, all idea of permittivity and rigidity being thrown away.

We compare magnetic force $\mathbf{H}$ in a pure conductor with the velocity $\mathbf{q}$ in a viscous liquid; the inductivity μ with the density of the liquid, so that the magnetic energy and the kinetic energy are compared, and the current is twice the spin. Also the source $\mathbf{f} = \text{curl}\,\mathbf{e}$ in the case of the conductor is compared with circuital impressed force in the liquid. So far is the same as in § 146. But now, in addition, we have the electric resistivity k^{-1} represented by the liquid viscosity. We conclude that the disturbances $\mathbf{q}$ generated by $\mathbf{f}_1$ in the liquid are similar to the disturbances $\mathbf{H}$ in the conductor generated by $\mathbf{f}$, and that the propagation of electrical disturbances in a conductor is like that of motion in a viscous incompressible liquid. It takes place by the process called diffusion. It is the limiting case of elastic wave-propagation, with distortion and dissipation of energy by friction.

We are usually limited to small motions in this analogy, so that the impressed forces should not act in one sense continuously, but should fluctuate about the mean value zero, for the reason mentioned before. But we are not always limited to small motions. In certain symmetrical distributions of magnetic force and current we may remove this restriction altogether. In the liquid case (333) p strictly means $\delta/\delta t$, whilst in (332) it means d/dt. In the former a moving particle is followed; in the latter we keep to one place. But in the cases of laminar flow referred to, $\delta/\delta t$ reduces to d/dt readily enough, so that the analogy is carried on to cases of steadily acting impressed forces.

The analogy is an important one, owing to the readiness with which the setting in motion of water by sliding friction can be followed, as when a wind blows over its surface. Two interesting cases are the penetration of magnetic induction and (with it) electric current into a core enveloped by a solenoidal coil, in whose circuit an impressed force, variable or steady, acts; and the penetration of magnetic induction and electric current into a straight wire when an impressed force acts in its circuit. Considering the latter we may state the analogy thus. Understanding, in the first place, that the circumstances should be such that the influence of electric displacement outside the wire is negligible, we may replace the wire by a similar tube of water, and then replace the impressed voltage in the electric circuit by a uniform tangential drag upon the surface of the water in the direction of the length of the pipe. The current of water in the pipe and the electric current in the wire, will vary similarly under the action of similarly varying impressed forces. Thus, a steadily applied force on the water will first pull the outermost layer into motion; this, by the viscosity, will pull the next layer, and so on up to the axis. The initial current is purely superficial; a little later we have a central core in which the water is practically motionless, surrounded by a tubular portion whose outermost layer is moving rapidly, and innermost very slowly; later still, the whole mass is in motion, though less rapidly at the axis than at the boundary; finally, the whole mass of water acquires a state of uniform motion. Substituting electric current for current of water, we obtain a representation of the way the electric current is set up in a wire, passing through the various stages from the initial surface current to the final uniformly distributed current. If the impressed force be rapidly oscillatory, we stop the penetration as above described in its early stage, so that if the frequency be great enough, there is a practical confinement of the current (in sensible amount) to the skin of the wire (or of the water respectively). But if the mean value of the oscillatory force be not zero, it is the same as having two impressed forces, one steady, the other periodic, without any bias one way or the other. Then we have finally a steady current throughout the wire, *plus* the oscillatory current with superficial concentration.

When a straight core is magnetised in a solenoid, it is the magnetic induction which is longitudinal, or parallel to the axis. Comparing this with the current of water in the pipe, we have the same state of things as before described, as regards the penetration of magnetic induction into the core.

One effect is to increase the resistance of a wire when the frequency is great enough. It will be remembered that Prof. Hughes (in 1886) brought forward evidence of this increase, and, therefore, in the opinion of others, of the truth of the theory of surface conduction along wires under certain circumstances which was advanced by me a year previous. There has since been plenty of confirmatory evidence of a more complete nature; that is, not merely of an approximation towards, but of an almost complete attainment of surface-conduction.

Digitized by Google

This action of conductors is sometimes referred to as magnetic screening. It should, however, be noted that the screening is done by the conductor itself, not by the currents "induced" in the outer part of the wire or core, which are, as it were, merely a sign that the screening is taking place. The screening action often seems to be merely superficial; but this is accidental, from the disturbances being communicated to the conductor from without. In reality, any and every part of a conductor is screened from the rest by the portion immediately surrounding it, that is, by its skin, and by that only. It is primarily the conductivity that causes the screening, so that it is rather conductive screening than magnetic screening. The result is that disturbances can only pass through a conductor by the (relatively) very slow process of diffusion, so unlike that by which they are transferred through a non-conductor. But the property of conductivity acts conjointly with the inductivity, so that although copper would be the best screener on account of its high conductivity, the great inductivity of iron usually far more than compensates for its inferior conductivity, and makes iron take the first place as a screener.

§ 150. As we were not able to make an analogy with c and k both finite, likewise n_0 and n_1, when $\mathbf{H}$ was taken to be velocity, let us try the effect of taking $\mathbf{E}$ to be velocity, as in § 147. Change the source from $\mathbf{f}$ to $\mathbf{g} = -\operatorname{curl}\mathbf{h}$; then we have merely to alter cp in (328) to $k+cp$ to obtain the required modification. Thus,

$$\mathbf{g} = \left((k+cp) - \frac{\nabla^2}{\mu p}\right)\mathbf{E} = \left((kp+cp^2) - \frac{\nabla^2}{\mu}\right)\mathbf{A}, \quad . \quad (334)$$

if $\mathbf{A} = \mathbf{E}/p$. Here, again, on comparison with (329), we see that distortional friction will not furnish a proper analogy in the general case. There seem to be but two special cases possible; first, with the conductivity and frictionality both zero (not the resistivity and frictionality), which reproduces the case in § 147; and, secondly, the permittivity and the rigidity both zero (not permittivity and compliancy), which brings us to the viscous liquid again. Thus, putting $c=0$ in (334) brings us to

$$\mathbf{g} = \left(kp - \frac{\nabla^2}{\mu}\right)\mathbf{A}, \quad . \quad . \quad . \quad . \quad . \quad (335)$$

which compares with (333). We now compare conductivity with density, and inductivity with the reciprocal of the viscosity. This is by no means so useful as the previous form of the viscous fluid analogy, although it is fundamentally of the same nature, involving propagation by diffusion.

As in §§ 146, 147, we had a failure of representation of one of the energies by the energy of distortion, so now, in the viscous fluid analogies, we fail to represent the dissipation of energy properly. This depends, as shown before, on the velocity of distortion, so we might expect a similar failure.

§ 151. But we can get a working analogy to suit the conducting dielectric in another way. Thus, still keeping the distortional elasticity or rigidity, give up the viscosity or distortional friction, and substitute translational friction. For the equation of motion of an incompressible solid with the usual constants, rigidity n and density ρ_2, and with translational frictionality ρ_1 is

$$\mathbf{f}_1 = (\rho_1 p + \rho_2 p^2 - n\nabla^2)\mathbf{G}, \quad . \quad . \quad . \quad . \quad (336)$$

where $\mathbf{f}_1$ is circuital impressed force. Now operate on (331) by $1 + k/cp$, producing the equation

$$\left(1 + \frac{k}{cp}\right)\mathbf{f} = \left(\frac{\mu k}{c}p + \mu p^2 - \frac{\nabla^2}{c}\right)\mathbf{Z}. \quad . \quad . \quad (337)$$

Comparing this with (336) we see that there is a proper correspondence of form on the right sides, though not on the left. The circuital impressed force $\mathbf{f}_1$ is replaced, not by $\mathbf{f}$, but by $\mathbf{f} + k\mathbf{f}/cp$. This is awkward for the analogy as regards the generation of disturbances. But away from the sources, there is a useful correspondence. As in § 146, $\mathbf{Z}$ corresponds to spacial displacement in the solid, $\mathbf{H}$ to velocity, μ to density, c to compliancy (distortional); whilst now, in addition, the translational frictionality in the solid has the complex representative $\mu k/c$ in the dielectric; or $k(\mu v)^2$, if v is the speed of propagation of disturbances. So disturbances of $\mathbf{H}$ are propagated in the same way through a conducting dielectric, as are disturbances in an incompressible solid with the usual rigidity, with frictional resistance to displacement superadded. But we do not correctly localise the energy dissipated. The rate of waste per unit volume is $k\mathbf{E}^2$ in the dielectric, whilst it is $\rho_1\mathbf{q}^2$ in the solid, which corresponds to $k(\mu v)^2\mathbf{H}^2$ in the dielectric. This being entirely against Joule's law renders this form of analogy unsatisfactory. But we may easily make a substantial improvement by taking $\mathbf{E}$ to be velocity in the solid.

§ 152. Thus, let $\mathbf{g} = -\operatorname{curl}\mathbf{h}$ be the source of disturbance in the dielectric, so that we have the equations (334) to consider. Take the second form and compare it with (336), and we see at once that there is a considerably more simple correspondence than in the case last treated. Thus, the source $\mathbf{f}_1$ of circuital displacement $\mathbf{G}$ corresponds to the source $\mathbf{g}$ of circuital $\mathbf{A}$ (the time-integral of $\mathbf{E}$); the electric force now means velocity; μ is compliancy; c is density; k itself is the frictionality; the electric energy $\frac{1}{2}c\mathbf{E}^2$ is kinetic energy; and the waste (Joulean) is properly localised in the solid by the frictional waste of energy $\rho_1\mathbf{q}^2$ per second. The induction $\mu\mathbf{H}$ is twice the rotation. In fact, this case is the same as in § 147, with translational friction added without destroying the analogy. It is clear that the correct localisation of the waste, and the correspondence of sources, makes the analogy be more readily followed. Of course, there is the same failure as regards the distortional energy as in § 146.

§ 153. As a last example in which use is made of distortional elasticity, let us generalise the non-conducting dielectric by the introduction of magnetic conductivity. We have

$$\operatorname{curl}(\mathbf{H} - \mathbf{h}) = (k+cp)\mathbf{E}, \quad . \quad . \quad . \quad (338)$$

$$\operatorname{curl}(\mathbf{e} - \mathbf{E}) = (g+\mu p)\mathbf{H}, \quad . \quad . \quad . \quad (339)$$

where g is the magnetic conductivity. So, if $\operatorname{curl}\mathbf{h} = 0$, and we eliminate $\mathbf{E}$, we have

$$\operatorname{curl}\mathbf{e} = \left((g+\mu p) - \frac{\nabla^2}{k+cp}\right)\mathbf{H}. \quad . \quad . \quad (340)$$

Or, if $\operatorname{curl}\mathbf{e} = 0$ and we eliminate $\mathbf{H}$, we have

$$-\operatorname{curl}\mathbf{h} = \left((k+cp) - \frac{\nabla^2}{g+\mu p}\right)\mathbf{E}. \quad . \quad . \quad (341)$$

We see that we cannot, when k and g are both finite, get a satisfactory analogy as regards the generation of disturbances by $\mathbf{f}_1$, circuital impressed force in a solid. Consider, therefore, only the free propagation, subject to the equation

$$0 = \left((k+cp)(g+\mu p) - \nabla^2\right)\mathbf{Z}, \quad . \quad . \quad (342)$$

where for $\mathbf{Z}$ we may substitute $\mathbf{H}$ or $\mathbf{E}$ or other electrical quantities. Since, in (342), we have a term proportional to $\mathbf{Z}$ itself (or its substitute), we must introduce elastic resistance to displacement in the elastic solid to make an analogy. Thus,

$$\mathbf{f}_1 = (\rho_0 + \rho_1 p + \rho_2 p^2)\mathbf{G} - n\nabla^2\mathbf{G}. \quad . \quad . \quad (343)$$

is the equation of motion in the incompressible solid if there be elastic and frictional as well as inertial resistance to translation, by (307), (313), § 145.

Now expand (342) and divide by c. We get

$$0 = \left(\frac{kg}{c} + \left(g + \frac{k\mu}{c}\right)p + \mu p^2\right)\mathbf{Z} - \frac{\nabla^2}{c}\mathbf{Z}, \quad . \quad (344)$$

which is suitable for comparison with (343). When $\mathbf{Z}$ is the spacial displacement, $\mathbf{H}$ is velocity, c compliancy, μ density, as in § 146; but in other respects the correspondence is complex, for the elastic resistance to translation ρ_0 is kg/c, whilst the frictionality ρ_1 is $g + k\mu/c$.

If we take $\mathbf{E}$ to be velocity there will be another set of correspondences, c being density and μ compliancy.

However unsatisfactory the analogy may be in details, we have still the result that disturbances in a dielectric with duplex conductivity (electric and magnetic) are propagated similarly to motions in an elastic solid constrained in the manner above described. The effect of the two kinds of distortion and waste of energy involved in the existence of the two conductivities are therefore imitated by one kind of frictionality in the elastic solid.

Digitized by Google

The singular distortionless case comes about when

$$\left.\begin{array}{ll} \rho_0\rho_2 = \rho_1^2 & \text{in the solid} \\ k/c = g/\mu & \text{in the dielectric.} \end{array}\right\} \quad \ldots \quad (345)$$

In either case the effect of the frictional resistance on the disturbances is made merely attenuative. Disregarding the attenuation with the time, the propagation takes place in the dielectric in the same way as if it were non-conducting, and in the solid in the same way as if it were devoid of frictional resistance. In the electromagnetic case we may follow this into detail with ease in a symmetrical manner. It is, however, rather troublesome in the elastic solid, on account of the want of correspondence in detail, due to the employment of distortional elasticity, and for other reasons.

(To be continued.)

THE DIMENSIONS OF PHYSICAL QUANTITIES.

BY W. M. M.

The publication last month of Mr. Williams' Paper "On the Relation of the Dimensions of Physical Quantities to Directions in Space," and the impending discussion thereon at the Physical Society, has raised afresh the recurring question as to the meaning of these dimensional equations, and the cognate question of the products and powers, integral, negative, and fractional, of concrete quantities.

There has always been a considerable body of mathematicians and physicists who have utterly refused to take what Mr. Williams calls "a most comprehensive and fundamental view of the matter." To these the dimensional formulæ remain still, what by general consent they are primarily, numerical relations between the units. They admit that they have no clear conception of the process of multiplying a force by a length, though they fancy they have a very clear conception of "a couple" and of "work;" and they even venture to doubt if anyone else really can picture to himself the square root of the product of a length into a mass. They have, however, for the most part, been content to wait in silence, expecting the pioneers of this new philosophy either to establish their position or to abandon it. They wait in vain. The so-called physical equations are neither admitted to be mere "change ratios," nor satisfactorily shown to be something more. They are *assumed* to be more, and the difficulties which inevitably arise are attempted to be met by fresh elaborations, such as giving a physical meaning to coefficients which are originally, by definition, numerical quantities, as μ, k, and even π.

Were the matter in debate primarily a physical or mathematical question, the authority of Lord Kelvin, the foremost physicist, and one of the foremost mathematicians of our day, would be almost conclusive. We say *almost*, for in science we admit of no pope, however eminent, and not the least of the many debts we owe to Dr. Oliver Lodge is his practical demonstration that, even on a physical question, Lord Kelvin's authority may be successfully opposed. But we hope to be able to show that this is not really a physical question at all, but a question of language and logic; and, though a mathematician is likely to be a sound logician, he is by no means necessarily so.

Ratio is defined by Euclid as "the relation between two quantities *of the same kind* in respect of magnitude." It follows that in order that two quantities may be equal (*i.e.*, bear one to the other a ratio unity) they must be of the same kind. Hence, in such an equation as $s = \frac{1}{2}ft^2$, either the symbols employed must be numerical quantities, or, if they are concrete, since s is a length ft^2 must also be one.

Now, it is admitted on all sides that, in the primary sense of the words, the statement that *an acceleration multiplied by the square of an interval of time is equal to a length*—is nonsense; it is using words whose corresponding ideas will not go together. But the suggestion is that, as Clifford said in a similar case, we should "treat it as if it were sense, and see what comes of it." This method is by no means new, nor do we think it always deserves to be described as "logically false and educationally mischievous."

When applied to the multiplication of fractions in arithmetic, or the interpretation of negative and fractional indices in algebra, "what comes of it" is a modification of our definitions in such a way that what seemed nonsense becomes sense. The question then arises, can any definition of multiplication be framed which will cover such cases as the above? If it can be, it is remarkable that it has never been done, though an attempt in that direction was made four years back by Prof. A. Lodge. But, even if it were done, it is doubtful if there would be any great advantage to be derived from it, since every equation is equally intelligible without such a refinement.

But we doubt altogether the possibility of framing such a definition. Recollect that it must be such as to cover every case. Thus—Economists used to tell us that the number of marriages in a community varies as the price of corn. (Whether they were stating a true law is not to the purpose.) It is clear that by a proper choice of units this variation may be made into an equation; but who would venture on the task of constructing the dimensional equation which would make this a relation between concretes? But we are unwilling to pursue this line of argument. The *reductio ad absurdum* method is a valid one in geometry, for the absurdities there appealed to can be appreciated without the aid of a sense of humour; but burlesque is altogether wasted on those who, with Professor Garnett, can gravely state the dimensions of *price* in *oranges*.

But suppose we agree, without waiting for an extended definition of multiplication, to treat nonsense as sense, and see what comes of it. We get from one definition of unit force that force is of dimensions MLT^{-2}. From another definition it is of dimensions M^2L^{-3}, and both definitions are equally admissible. Is it not clear from this that the dimensional formulæ do not "represent the *physical identities* of the various quantities," but only indicate at most the conventions we have adopted, as to our system of units and our mode of measurement. Similarly *resistance* comes out as either a *velocity* or a *slowness* according to the system adopted; it clearly cannot be both, but it may very well be neither.

But much worse than this "comes of it." It has been well said that "mathematics may be compared to a mill of exquisite workmanship, which grinds you stuff of any degree of fineness; but, nevertheless, what you get out depends on what you put in." Into our electrical and magnetic dimensional formulæ we put—the assumption that our units shall be systematic; the law of the inverse square as true for static charge and for magnetic poles; the fact that an electric current produces a magnetic field, also following the law of the inverse square; and the unproved assumption that a current is a *flow* of whatever causes static charge. What we get out changes from day to day, but at present it includes—that electricity is ether, that resistance is a velocity, and that the coefficient of self-induction is a length. Respecting the last point it may be noted that the tone of our opponents has changed somewhat. Formerly they were almost apologetic, and spoke of resistance as "of the nature of velocity," whatever that may mean. Now they are very positive. "But it"—*i.e.*, self-induction—"*is* a length," as one of them said at the last meeting of the British Association.

We wonder whether this impatient dogmatism covers secret misgivings. We almost think it must be so, for at the commencement of the discussion on Mr. Williams' Paper the same gentleman alluded, in a tone with which we entirely sympathise, to the absurdity of trying to attach any physical idea to such expressions as $M^{\frac{1}{2}}$ or $L^{\frac{1}{2}}$. But when he added that the *only* way out of the difficulty was on the lines that Mr. Williams laid down, we were no longer with him. It seems strange that it never even occurred to him that while the square root of a *mass* was unintelligible, the square root of a *ratio* presents no difficulties whatever.

To sum up. We quite admit that a physical quantity consists of two parts, its measure and its concrete unit; but we deny that, in general, the latter can enter into an equation. We do not object to the equation $s = v\,t$ being written $s[\mathrm{L}] = v[\mathrm{V}]\,t[\mathrm{T}]$, but we deny that [L], [V], [T], are, *in this equation*, concretes. They are the numerical measures of our units in terms of new units. We do not object to suppressed dimensions, for we prefer to suppress them all. We regard these physical

Digitized by Google

equations as a hindrance instead of a help in education, since they are one more step in the direction of making our symbols do our thinking for us; and of this there is already too much in mathematics. It is noteworthy that the enthusiasts for these methods almost always complain that "students usually find peculiar difficulty in questions relating to units." We are not surprised, nor do we think it is altogether the fault of the students. We never met anyone so dull that he could not understand the proverb, "The more the merrier, *the fewer the better fare.*" Yet the latter part of this expresses exactly the same idea as the more pretentious sentence, "The numerical value of a concrete quantity varies inversely as the unit in terms of which it is expressed."

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(*Continued from page 214.*)

14. Cable Splice.—Before the splice in the sheathing wires is made, the core is served with a layer of tape or loose spun threads, over which is laid a serving of brass tape, followed by jute, yarn, or Russian hemp, bound at intervals with seizings of fine yarn. The splice is then begun on the right side, laying the wires close together by means of the splicing tool (Fig. 44). This tool is made in steel plate, with notches in the form of two half circles, in which the sheathing wires are placed. The tool is opened in the middle to set it in position across the cable and put the wires in order in their respective notches, and is then closed up and fastened by a small set screw and nut. It is then worked round by the handles in the direction of the lay, and in this manner the wires are forced round the cable in their proper places spirally, exactly similar to the other part of the cable. Little by little as the tool is worked round it is pushed forward along the cable; for example, in the deep-sea type the lay of the sheathing wires being ten inches, the tool would advance ten inches for one complete turn round cable. With steel wires the work is much more difficult than with galvanised iron, as the spring of the steel exerts a considerable resisting force to the twist. As the tool is worked along it is followed up in places by seizings of yarn round the cable to keep it from springing back.

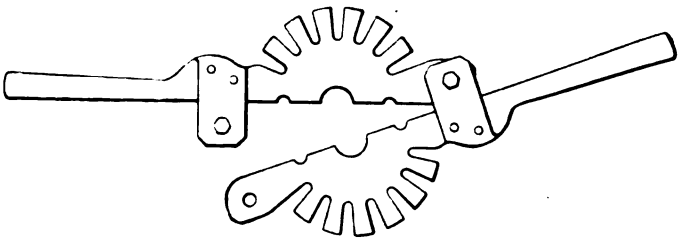

Fig. 44.—Splicing Tool.

In Fig. 45 this tool is shown in position as used, the sketch representing the operation as nearly completed on the right wires. As soon as the tool is worked round to the end of the wires, that is, to where the left wires are unlaid, a final seizing is put on about 4in. from the end, and the tool removed. With a hand-cutting tool the ends are then snipped off perfectly equal in length. The left wires are now taken in turn, and every two wires alternately if small, or every one alternately if large wires, are snipped off short, so as to exactly butt the ends of the right wires. The alternate pairs of wires remaining on the left side, which are all about 90ft. in length, are then laid in turn on the right side, corresponding pairs of right wires being unlaid to receive them. Take, for instance, one such pair. It is first of all noticed which pair of right wires lies in the same lay as the pair of left wires we are considering. This pair of right wires is then unlaid for some distance, say 50ft., and the corresponding pair of left wires threaded in under the seizings, so as to lay in the place thus vacated for them. One wire of the left pair, and one wire of the right pair, which lie in the same lay, are then snipped off so that their ends lie exactly butt together. The single right wire that remains is

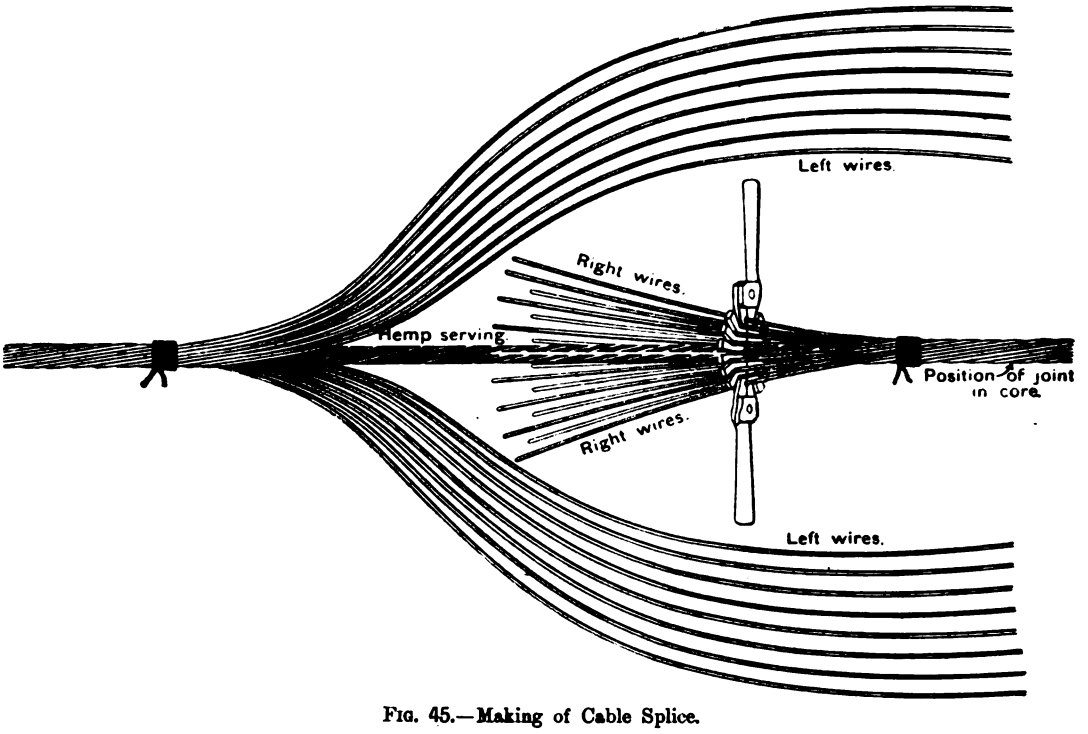

Fig. 45.—Making of Cable Splice.

Fig. 46.—Finished Splice in Sheathing Wires.

* All rights reserved.

Digitized by Google

then further unlaid, and is followed up by the remaining left wire, which is laid in the place vacated by it. This is continued for about 40ft. further, when the ends of both wires are snipped, so as to lie butt together. The next pair of wires is then taken and treated in the same manner; this time the wires being cut at shorter distances than the above, so that the butted ends do not all lie near together. The next pair follows, and the wires are cut at still shorter distances than the preceding ones, and so on to the last pair; the procedure in this respect

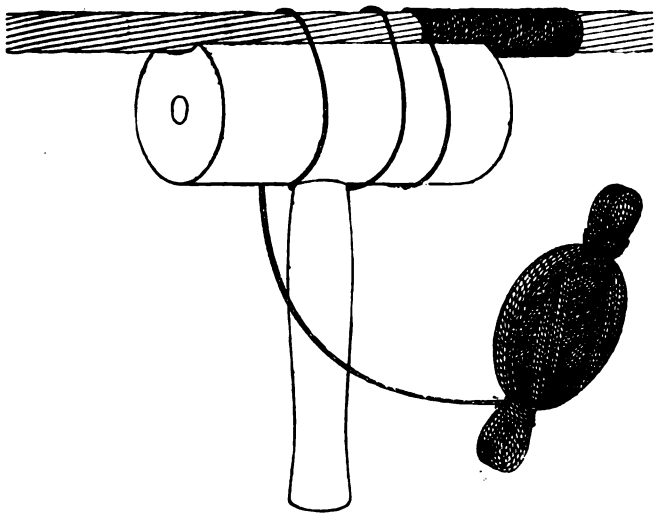

Fig. 47.—Serving Mallet.

being similar to that in manufacture, when no weld in any of the sheathing wires is allowed to be nearer than ten feet to any other weld in the same or any other wire. With the left wires 90ft. long as given above, and with 16 sheathing wires as shown in the illustration, there would be eight wires carried over on to the right side, and the butt joints between these and the right wires would be at distances of about 11ft. apart.

The appearance of the splice so made is represented in Fig. 46, where the left wires are shaded, so that their course can be traced and understood. Necessarily, in the sketch, for want of room, the splice is shown much shorter in length relatively to the size of cable and sheathing wires than it should

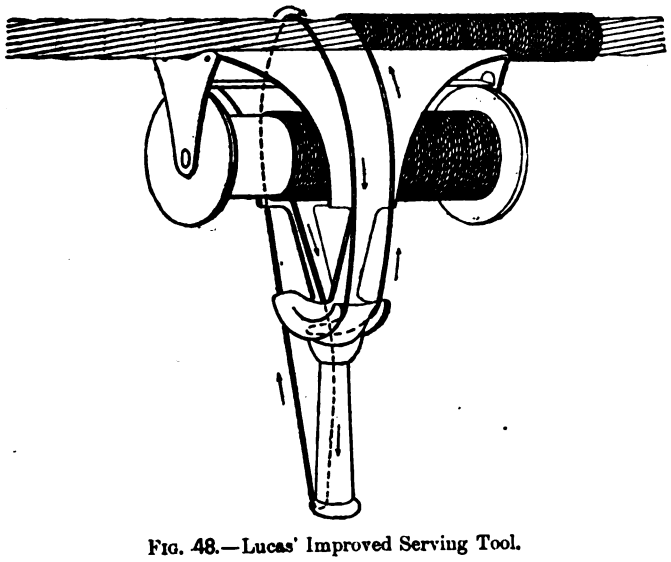

Fig. 48.—Lucas' Improved Serving Tool.

be, but it serves the purpose of making the manner of splicing understood. In splices made at the factory between very different types of cable such as the deep-sea and intermediate portions, the sheathing wires of the larger cable are tapered down to the size of the smaller. Apart from the great length of the cable splice, so made for the purpose of distributing the strain, it will be noticed that it differs from the sailor's rope splice, in which he remembers he must—

"Worm and parcel with the lay,
Turn about and serve t'other way."

Again, it will be noticed that the joint in the core is covered by the pairs of right and left wires laid together, and is some distance away from the place where the alternate pairs butt. Over all butts are wrapped seizings of ductile wire.

It now only remains to cover the whole with a serving of tarred yarn. For this purpose the serving mallet shown in Fig. 47 has long been in use. The mallet is represented in the sketch in position for serving, one man turning the mallet round by the handle while his mate follows round with the ball of yarn. Pairs of men are stationed along the splice, who commence serving at different points, and continue till they finish where their neighbours began, so covering the whole. The course of the yarn from the ball round the body and handle of the mallet to the cable is shown clearly in the sketch. By the half turn taken round the root of the handle, the round turns over cable and mallet are in opposite directions, which causes sufficient check on the yarn to render it taut on the cable.

An improved serving mallet has been introduced by Mr. F. R. Lucas, of the Telegraph Construction and Maintenance Company, which can be worked by one man. This is made in metal, and carries on a reel its own supply of spun yarn (Fig. 48). From the reel the yarn passes through the hollow handle, then round the cable, and back to the mallet, where it takes half a turn round the shank to keep it taut, and then returns to the cable in the opposite direction, round which it is fed in a continuous spiral as long as the mallet is turned round. The splice, which may have occupied altogether two hours, is now complete, and after a final test through is ready to be dropped overboard.

(*To be continued.*)

RESISTANCE STANDARDS.*

The author considers that the standard of resistance is the most valuable that we have, being the only one that has any physical tangible existence. The wire for standard coils should have high specific resistance to avoid large bulk, and as small a temperature coefficient as possible; it must not change with time either from oxydation or other cause, and it must be of a hardness suitable for handling in manufacture without injury. These requirements at once throw out all pure metals, and compel us to have recourse to alloys. The B.A. Standards Committee, after exhaustive experiments from 1862-5 on various metals and alloys, finally concluded that silver alloyed with 33·4 per cent. of platinum was the best for the purpose, and it is still largely used; its specific resistance is, the author says, 14 microhms, and its T.C., 0·031 per cent. (or under one-tenth that of copper, not one-hundredth as the author puts it). Many metals seem to alter in resistance with time and heating. Bergman in 1889 kept various metals at 300°C. for an hour and found that they had all altered, copper having decreased 2·4 per cent. and German silver increased 0·2 per cent. The platinum silver standards of the B.A. Committee were found last year to have increased about 0·06 per cent. The committee suggest that this change is due to strains in lowering the coils to 0° for the test. Time changes, however, do undoubtedly occur in metals even when not subjected to any such stresses. Winding a wire on a bobbin necessarily changes its form somewhat and also its resistance, and such strains take a long time to settle down; for which reason coils have to be kept some months before final adjustment.

The author then refers to platinoid, which he says he has several times analysed, but in which he has never found any of the two per cent. of tungsten which it is said to contain. Be this as it may, it has the properties claimed for it, a T.C. of 0·022 per cent. (not $\frac{22}{100}$ as said), and a specific resistance of 32 microhms.†

The author then refers to a new wire sent him by the Aluminium Brass and Bronze Company of Bridgeport, Conn., which is claimed to have a specific resistance of 56 and a T.C. of less than 0·004. It appears to contain a considerable amount of copper, and is possibly about 70 copper to 30 manganese, with perhaps a little nickel. Drs. Feussner and Lindeck (*Zeits. Instrk.* Feb. 1891) state that an alloy of 70Cu and 30Mn has a negative T.C. of 0·003 per cent. So that it appears probable that an alloy may be got with a zero T.C., a consummation devoutly to be wished.

* Abstract from a Paper by E. G. Willyoung before the Franklin Inst.

† The T.C. (temperature constant) varies from 0·017 for very fine wire to 0·025 for wires of 0·02in. to 0·03in. The T.C. does not follow the size in any exact law, but the connection is unmistakable. The specific resistance also varies. I have generally found it to average about 38 or 39, but it varies from 30 to 45.—C.W.S.C.

TESTS OF EDISON-SWAN LAMPS.

A large number of tests of the candle-power, efficiency and resistance of glow lamps have been made both in the United States and on the Continent, and have served a useful purpose in showing the general character and properties of different kinds of lamps. But it is remarkable that while in this country we have been tied so exclusively to one make of lamp, and one only, no tests of that lamp have been published. That the publication of such data has not been encouraged by the makers can have little to do with the absence of any such literature, and it can only be explained by the well-known fact that what is everybody's business is nobody's business. In the recent LANE-FOX action, some figures showing the candle-power and life of lamps, presumably of EDISON-SWAN make, at different voltages, were given by one of the witnesses. The life of lamps is fully as important as their candle-power, since these two factors enter into the total cost of lighting; but accurate determinations of life cannot be arrived at except by very considerable trouble, even if assisted by meters, and no one, so far as we know, has attempted to carry out really careful and complete experiments on the duration of lamps at higher or lower voltages than the normal. Not only must such observations of necessity be spread over a considerable period, but they must be carried out on a sufficiently large number of lamps to ensure a fair average. For it is well known that out of a number of lamps which agree well together in candle-power at any given voltage, and which in fact do what the makers' marks say they will do; the life, that item about which the makers say nothing, may vary enormously. Some lamps will give out in the first twenty or thirty hours, and others will have a phenomenal existence. Much more care should, therefore, be taken in examining the life of lamps, to eliminate accidental values, than is needed in measuring those characteristics which are a simple matter of laboratory work. Besides the actual life of the lamp as a lamp, there is the very important question of the gradual change in the candle-power, culminating at a point at which it is better to throw the lamp away than to continue to burn it at a low efficiency.

Digitized by Google

Electrical engineering, as we recently observed, is becoming desperately scientific, and we expect to see every physical quantity expressed in figures, and every physical fact in a formula. From one point of view, a knowledge of the candle power of a glow lamp at a given voltage, and its life at that voltage, seems a perfectly indispensable starting point in dealing with the cost of electric lighting; so indispensable, in fact, that not only elaborate experiments ought to be made, but a considerable amount of theory is warrantable. But we have a bare theory of minimum expenditure, and no data whatever for applying it. On the other hand, it might be imagined by a sufficiently thoughtful and ignorant person, that a manufacturing engineer would have an accurate knowledge of tool-speeds, drill-feeds, and the life of tools and the cost of grinding them. But most of them trust their foremen to see after these details, and not a few foremen leave such matters where they found them, picking up occasional hints about the possibilities of tool-speed on piecework, and merely avoiding extremes in the matter of grinding. So with glow lamps, we have been content to do without accurate knowledge, and to trust the makers. The makers of the glow lamp, to which patent laws have tied us for so many years, may indeed flatter themselves that when we ask for a 16-candle lamp, we do not "see that we get it," but we take their word for it, and we are equally accommodating in the matter of durability, about which no promise whatever is made.

Tests of ordinary EDISON-SWAN lamps have been carried out by some students at the Central Institution, a report was drawn up by them at Easter, 1891, and we are enabled by the kindness of Prof. AYRTON to publish the results in our present issue. It should be observed that the lamps were of the ordinary pattern, bought from the EDISON-SWAN Company in the usual way, and tested at once while quite new. Several previous tests of glow lamps had been made at the Central Institution, and it is easy to see from the report that the students had a competent knowledge of the use of the apparatus, and that their results may be accepted with confidence. Several sheets of curves accompany the report, and some of these are reproduced, but we can only find space for a few of the actual observations as samples. It will be observed that the stated figures are not borne out by the tests. Lamp No.2 02, bought as a 100-volt lamp, appears to be better adapted for 105 volts. It would be a pleasure to publish such an abstract as this if only to show what careful work is being done under Prof. AYRTON; but the information contained in it is of very considerable interest even to the most rule-of-thumb electrician, and the fact that the first patent of those which lock up the lamp-making industry expires in some eighteen months, makes the publication of these results of no less importance.

OBITUARY.

MR. CYRUS WEST FIELD.

We regret to record the death of Mr. Cyrus West Field, in his 73rd year, at New York, on the 12th instant.

The world has grown so accustomed to the constant interchange of submarine cable messages that there is some little likelihood of the important part which he played as the pioneer of ocean telegraphy being overlooked. It is not too much to say that, had it not been for his bold conception of bridging the Atlantic by the electric wire, and the marvellous energy which he displayed in practically giving effect to the idea, telegraphy under the greater oceans would have been carried out many years later than it actually was.

The late Mr. Field was one of the several sons of Dr. David Dudley Field, D.D., who himself was born in the State of Connecticut—almost simultaneously with the recognition of the United States as a Republic—in 1781. The eldest son, who bears his father's name, is still living, and is one of the foremost jurists the New World has yet produced. Another son, Mr. Stephen Johnson Field, became Judge of the Supreme Court and, finally, Chief Justice of California. Another of the late Mr. Field's brothers is the Rev. Henry Martin Field, who was editor and proprietor of *The Evangelist*, of New York, as well as author of several books, including "A History of the Atlantic Telegraph," "A Chronicle of the Irish Rebellion of 1798," and a History of Rodney's successful Defence of Gibraltar. The most famous son, however, of the Rev. Dr. Field was the indefatigable "promoter" of the Atlantic cable. Born in Massachusetts in 1819, and educated in his native State, he was the only member of the family who was brought up to a commercial life. At the age of fifteen he went to New York, and commenced his business life in the colossal dry goods stores of Alexander T. Stewart. When just twenty-one he began on a large scale the manufacture and sale of paper. Having established a large and increasing business, at the age of thirty, when travelling in South America, he conceived the idea of connecting Europe with Newfoundland, and the latter island with New York by submarine cable. Assisted by four of the most influential capitalists in New York, Mr. Peter Cooper, Mr. Moses Taylor, Mr. Marshall O. Roberts, and Mr. Chandler White, he showed the most indefatigable energy and persistence until communication was accomplished in 1858. He crossed the Atlantic some fifty times, and interviewed everyone likely to assist in carrying out the enterprise, including the late Mr. John Bright and Mr. Gladstone — the former of whom said that Mr. Field was "the Columbus of modern times, whose cable had moored the New World alongside the Old." Even when the cable, after working only a month, ceased to transmit messages, the late Mr. Field did not lose a jot of heart or hope, or abate the truly extraordinary energy and pertinacity of his efforts. The repair of cables in deep water was then thought to be impracticable, and Mr. Field was unceasing in his efforts to get a new cable manufactured and laid. In 1865 another effort was made to lay a cable, but the end being lost and no adequate apparatus for raising it existing, the attempt had to be abandoned. In the following year, 1866, the third cable was successfully submerged, and later in the same year the lost cable of 1865 was picked up and completed. Had Mr. Field been an English citizen, honours and decorations would have been offered him on this side of the Atlantic. At home the United States Congress voted him a gold medal for his exertions connected with Atlantic telegraphs; while a dinner was given in his honour at Willis's Rooms, London, when telegraphic messages were exchanged between the company present on the one side and Lord Monck, Viceroy of Canada, and President Johnson on the other. Mr. Field was a Director of the Atlantic and Anglo-American Telegraph Companies, as well as of the Falmouth, Gibraltar and Malta, the Anglo-Mediterranean, and the Globe Telegraph and Trust Companies. Mr. Field was also one of the earliest advocates of a trans-Pacific cable, which has not, however, yet been carried out.

Shortly before his death Mr. Field was interesting himself in a project for laying a cable from San Francisco to Honolulu, with a subsidy from the American Government, as the first section of a submarine cable to Australasia and Japan. He also advocated the formation of a giant company to absorb all the submarine cable companies in the world, which was not however destined to be realised. Mr. Field became an American millionaire, and for many years fortune seemed to smile upon him; but in November last he was prostrated by the death of his wife, who had lived to celebrate their golden wedding, and soon after he was almost ruined by the failure of his son's firm of stockbrokers, his son becoming insane. These troubles, together with the dangerous illness of one of his daughters, broke down Mr. Field's health; and after a long illness death ended a remarkable career, which illustrates the power of the man of a single idea, and entitles the late Mr. Cyrus West Field to be regarded as one of the great benefactors of mankind.

TESTS OF GLOW LAMPS.

The following is an abstract of a report on the efficiency, resistance, and candle-power law of six perfectly new Edison-Swan lamps, Nos. 200 to 205, drawn up by Mr. G. C. Turner, Mr. Lloyd, and Mr. Wicks, at the Central Institution of the City and Guilds of London, and dated at Easter, 1891. This report is a sample of a number which Prof. Ayrton's students have made on incandescent lamps of various types constructed in England and abroad :—

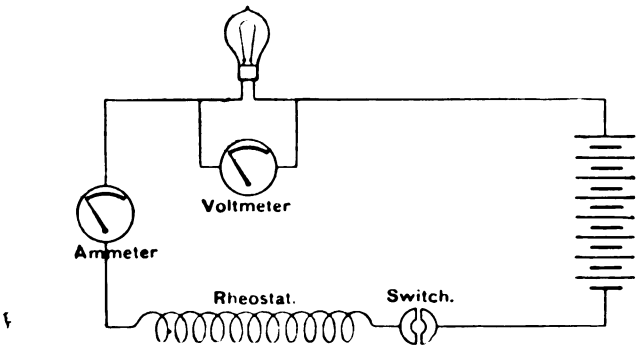
As in previous experiments on incandescent lamps, the standard of light was a Methven screen of 2 c.p., previous tests having shown that this agreed extremely well with the Harcourt's pentane standard. Distance between standard and lamp to be tested was 200 centimetres. Photometer used was a paraffin block photometer. During the experiment a series of observations were made to determine the errors of (1) reproduction ;* (2) photometer error ; (3) personal error. The test was made with lamp No. 203.

(1) Reproduction error.—Mean error was found to be 0·195 centimetre, which, as a percentage of the length of the bench, gives per cent. of error* = 0·097.

(2) Photometer error.—Mean error = 2·4 centimetres, *i.e.*, 1·2 per cent. of length of bench.

(3) Personal error.—Mean = 1·93 centimetres ; per cent. of error = 0·96.

The voltmeter was always placed as a shunt to the lamp, and the ammeter reading corrected for current passing through the voltmeter. In all cases when photometer readings were not taken by all three observers, the readings were corrected for personal error, so as to get approximately the reading which would have been obtained if all three had taken readings. In



all cases readings were taken first with photometer blocks facing one way, then with them facing the opposite way, so as to eliminate the error due to the blocks being unsymmetrical, or non-central. In all cases the readings given are the mean of three or four readings.

It was noticed that whenever the lamp had to be taken off so as to change the number of accumulators, the current, on putting lamp in circuit again, had decreased. Hence, it would seem that in order to take the readings so as to bring the lamp into a normal state for that reading the volts should be kept constant for some time before reading is taken, in order that the lamp may be in a steady state. In our experiments, owing to the great number of observations to be made, it was impossible to do this completely.

Resistances of the Lamps.

50-volt 8-c.p. lamps: ratio of resistance hot to resistance cold fell from 0·508 to 0·479 as the current was steadily increased.

100-volt 8-c.p. lamps, from 0·546 to 0·496.

100-volt 16-c.p. lamps, from 0·584 to 0·494 and 0·548 to 0·508.

In most cases, especially in the 50-volt lamps, the resistance shows a decided tendency to rise just before the normal voltage is reached. The resistances of these lamps seem to fall considerably more in proportion than is the case with old lamps ; for example, No. 3, for which lamp the ratio of resistance hot to resistance cold only fell from 0·52 to 0·49. The watts per candle at normal voltage varied from 3·8 to 4·0, except in the 100-volt 8-c.p. lamps, in which it went up to 5, showing a decided inferiority in the 8-c.p. lamps as regards cost of supply.

The candle-power of a lamp observed by this sort of photometer seems to depend to some extent on the exact part of the lamp bulb which faces the paraffin blocks, the inequalities of the glass having considerable influence on the observed candle-power, an exaggerated case being seen in lamp No. 14, previously tested, in which candle-power was doubled by the lamp being placed edge on instead of at an angle of 45deg. This would probably explain some of the irregular results obtained in the life test.*

Lamp No. 200.

Nominal volts, 50, Candle-power, 8. Single thin filament. Resistance when cold, 162·3. Carpentier galvanometer used as voltmeter, with 6,000 in B.A. box No. 12 + 770 in Harvey and Peak box. Ammeter No. 564. Filament broadside on.

Civil List Pensions.—The following are amongst the names in the Civil List Pensions granted by the Government last year:—Mrs. Caroline Emma Carpenter, £100, in consideration of the services rendered by her late husband, Dr. Philip Herbert Carpenter, F.R.S., to science and of the sad circumstances in which she has been left by his death; and Dr. George Gore, F.R.S., £150, in consideration of his services to chemical and physical science.

THE LUNDELL MOTOR.

A curious application of electrical energy is common enough in America, but is not likely, from climatic and other reasons, to be largely adopted in this country. We refer to the use of small motors for driving fans. Where punkahs or their equivalents are absolutely necessary such contrivances are undoubtedly useful; but we would rather suffer a good deal than add the whirr of a fan and the buzzing of a "desk motor" to the clatter of Salisbury-court and the roar of Fleet-street. It

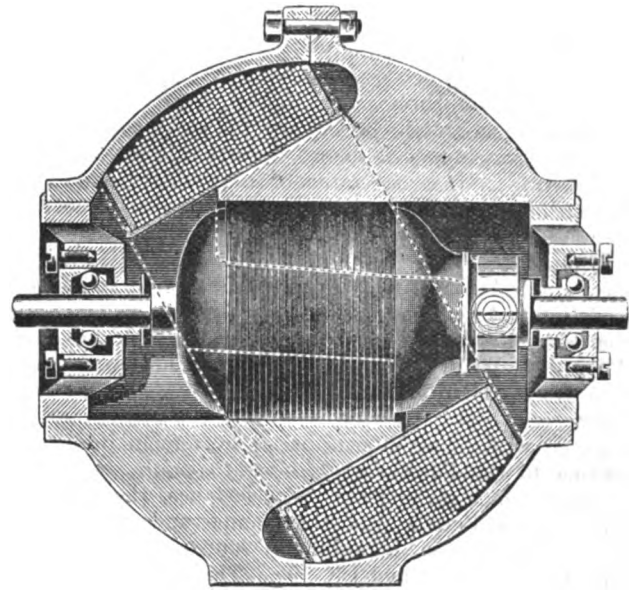

Fig. 1.—Lundell Iron-clad Fan Motor.

might be said, as was hinted by an American visitor to the City and South London Railway, that our air is not worth stirring. Be that as it may, the latest device for cooling the American brow has been brought out by the Interior Conduit and Insulation Company of New York. The magnetic leakage of small motors is said by this company to be very serious. Though at first sight the reason for this is not very evident, it is doubtless due to the fact that the cleavance between armature and pole pieces is by no means proportional to the other dimensions of a dynamo or motor, and is indeed almost a constant quantity.

The ironclad principle which, as has been pointed out more than once in *Industries*, is very much overrated, has been adopted, and a very ingenious arrangement of pole pieces and field magnets has resulted (Fig. 1). The armature (Fig. 2) is called a "Pacinotti drum," but seems to be rather a perforated armature with slots for facility in winding, like the armature of the magneto used with the Evershed ohmmeter. In the description of this motor which appears in the American

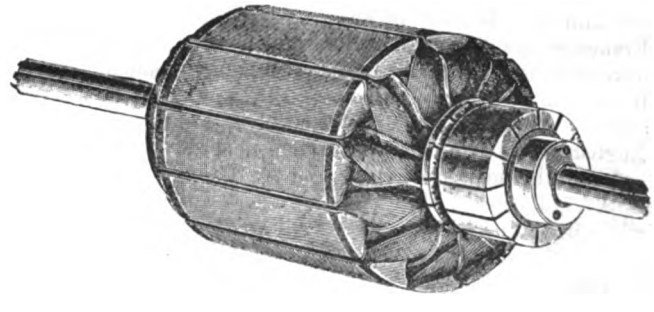

Fig. 2.—Armature of Lundell Fan Motor.

journals, it is said that the motor is sparkless, and the point of commutation remains fixed within the limit of load, and at reversal of rotation. The brushes are small carbon pencils. The $\frac{1}{12}$-H.P. size is fitted with ball bearings, and runs at a maximum of 1,800 revolutions per minute. On a 100-volt circuit they run at 900 to 1,150. Motors giving $\frac{1}{6}$-H.P. are also made.

THE PROPOSED FRENCH-AZORES (HAYTI) CABLE.

[COMMUNICATED.]

It will be in the recollection of those of our readers who are interested in submarine cable matters that the Portuguese Government granted a concession to the Société Française des Télégraphes Sous-Marins for the laying of a cable to the Azores. The matter is now about to be submitted to the French Chambers in the form of a project for establishing submarine communication from Brest to Lisbon, thence to the Azores, and on to the Island of Hayti. The cable, which is to be constructed in French factories, will be laid and worked by the Société Française, which possesses already 3,754 miles of cable connecting two or three of the foreign West Indian Islands with French and Dutch Guyana and the north coast of Brazil, and which Company, as is shown hereafter, is already in sore financial straits. In consideration of connecting the new system with that of the Antilles a subsidy or guarantee of traffic by the French Government of £92,000 per annum for 25 years is asked, plus £10,000 for maintenance, which latter is absolutely inadequate. Amongst the advantages expected to accrue to French interests in consideration of this very large payment is the creation of more rapid communication with the Antilles and South America. These countries are at present served by the North Atlantic lines, of which only one, the Pouyer-Quertier, is French. Beyond New York the communication is carried on with many intermediaries by foreign lines. This, according to the Paris *La Politique Coloniale*, explains the high tariffs which are in force. For instance, the charge per word between France and Guadaloupe and Martinique is 11f. 25c. and 15f. 65c., according to route; while for Guyana the rates are 13f. 35c. and 15f. 55c. The authors of the project claim that the creation of a direct and economical route will attract a considerable part of the traffic, and will, in addition, be advantageous to the French colonies concerned. Our French contemporary congratulates the Minister of Commerce upon his solicitude for the interests of the colonies, but points out that it would be more useful to connect with the mother country those dependencies which do not possess telegraphic communication than merely to reduce tariffs by laying competing lines.

Thus far our information has been obtained from French sources, and we may now proceed to consider what prospect there is for a cable which connects Brest with Lisbon, the Azores, and Hayti. Some source of revenue will undoubtedly be the traffic between Brest and Lisbon. The traffic between France and the Azores cannot be important, as there is hardly any trade. With the colonies of Martinique and Guadeloupe there are only a few messages a day; while those from Hayti by the new line will not amount to much. And there seems to be little doubt that the French Government will be called upon for the greater part of the amount of traffic guaranteed, as is the case with Portugal, which, under the guarantee of £41,900 for the cables on the West Coast of Africa, has to pay £27,000 per annum. By way of showing to what extent the Société Française des Télégraphes Sous-Marins are laying cables which have not the remotest prospect of securing an adequate revenue from traffic for many years to come, it will be of interest to analyse its last balance sheet, which, arranged according to English methods of account, stands as shown in next column.

It will be seen that the profit on paper for 1891 is shown as £3,711, but nothing has been set aside for depreciation, while in 1890 £4,575 was reserved on this account, nor has any part of the discount on the issue of debentures been charged to revenue. Further, only six months' interest on the debentures enters into this account, and as the debentures are repayable by annual drawings, the following amounts should have appeared:—

Depreciation (30 years' life)	£8,800
Sinking fund (debentures redeemable in 30 years)	2,137
One-thirtieth of the cost of issuing debentures	900
Total	£11,837

Thus turning the profits of £3,711 into a loss of £8,126. Again, during the year a sum of £20,167 was received from the Société Générale des Téléphones in respect of interest, guaranteed during construction, which sum the Société Française propose to pay to their shareholders in two halves. Apparently, however, the construction of the lines being now completed, the guarantee ceased with the year 1891, and the Company will be left to face a certain loss. The traffic is not likely to increase, while on the other hand interest on debentures will be £7,100 more, and the working expenses will be increased because some of their stations were not open during the whole of 1891.

All experience shows it to be hopeless to argue with the advocates of Protection; but if the French Chamber likes to make the whole community responsible to the extent of £102,000 annually for 25 years in the interest of the few artisans in the French cable factories, and cable promoters, it can only be regarded as an instance of Protection run wild. In fact, if all the minor industries in France were to be "protected" in like manner, even the enormous resources of that country would not bear the strain imposed upon them.

The truth is that unless the Government do something for the Société Française, which is hopelessly insolvent, that Company will have to be wound up, and it is evident that the guarantee of traffic and working expenses (which are to be deducted to the extent of £10,000 a year from the receipts for traffic before the guarantee is calculated) to the enormous extent of £102,000 per annum is calculated to provide a small dividend on the capital already expended, as the Company's existing lines must necessarily, unless the traffic grows, work at a loss of over £15,000 per annum.

A very liberal estimate of the cost of laying the projected sections, furnishing stations, &c., is £1,000,000; but the *exposé des motifs* submitted to the Chamber calculates the price at

Expenditure.	1891.	*Revenue.*	1891.

	£797,553		£797,553

* The item "special reserves" of £15,702 is misleading—it was not created out of revenue, but out of capital

Digitized by Google

£1,320,000. It would be very interesting to know what is to become of the odd £320,000. Do the French Government desire to "protect" the promoters or the Société Générale des Téléphones, the manufacturing company, by making them a present of that sum, the French taxpayer having to foot the bill by paying interest and amortisation upon it for 25 years?

Assuming the maintenance (which is to be to the extent of £10,000, a first charge on the receipts) at £15,000, amortisation fund for debentures £27,400, and expenses of repairs at £4 per mile per annum, we get the following result:—

Revenue.		*Expenses.*	
Traffic guaranteed	£92,000	Working expenses £15,000	
Maintenance	10,000	Amortisation Fund 27,400	
		Repairs 17,600	
			£60,000
		Net profit of new lines ..	42,000
	£102,000		£102,000

This profit shows a dividend of 3 per cent. on £1,320,000, or deducting the loss of £15,000 per annum on the old lines, 1½ per cent. on the whole share capital of the Compagnie Française, which will be £1,760,000, assuming the new capital to be entirely in shares, when the new sections are completed.

Again, it will probably be found necessary to raise some considerable part of the £1,320,000 (say half-a-million) in debentures, in which case interest at 5 per cent. would be £25,000, leaving only £2,000 to pay dividends on £1,260,000,

It has apparently been overlooked that by guaranteeing traffic on this new line between France and South America, the French Government will actually be subsidising a line which will be in competition with its own cable between the Canary Islands and Senegal.

The last advices show that the Budget Committee has reported against the project, which was not submitted to the Chamber before it rose on the 13th inst. Doubtless, if the matter ever comes before the Deputies they will see this proposal in its true light.

LONDON CHAMBER OF COMMERCE.

THE ELECTRICAL TRADE SECTION.

A meeting of the Electrical Trade Section of the London Chamber of Commerce was held at the offices, Botolph House, Eastcheap, on the 8th inst., under the presidency of Major Flood Page.

The SECRETARY (Mr. Kenric B. Murray) having read the minutes of the last meeting,

The CHAIRMAN stated that since the last meeting of the Section they had gone one step in advance in regard to the important question of electrical traction, and a day had been arranged when they would meet gentlemen on the opposite sides of the matter, with a view to seeing whether they could not save the expenditure of £100,000 in litigation. He dared not say that they were hopeful, but nevertheless they had arranged a meeting at which the National Telephone Company, on the one side, and the traction interests on the other, would be represented; and they were going to see whether it was possible to agree to some *modus vivendi*, and something should be done to avoid litigation, which, as far as they could see, would be very serious. They were told on the one hand that Leeds would settle nothing, and on the other hand that it would settle everything; and if, through the Chamber, they could come to some arrangement between the two parties, they would have accomplished something very great for electrical industry. He was going to ask the permission of the meeting to take the agenda out of its order, as Mr. Preece was compelled to go Wales, and that gentleman wanted to tell them what had been done with reference to the Chicago Exhibition. A committee had been appointed, and they had had a meeting, and he need only say that the result of that meeting was that they had determined to call the present meeting in order that Mr. Preece might inform them of how matters stood.

Mr PREECE said that up to the present time the prospects of a successful electrical exhibit at Chicago were very remote, while, on the other hand, the display of other industries was going to be a very great success. The most magnificent display ever despatched from this country to any Exhibition was going to be sent to Chicago. There were over 1,500 exhibitors, and the space allotted to them had had to be reduced. In the case of the Electrical Section, on the other hand, out of 20,000 square feet which had been allotted to it, only 5,000ft. had been taken up. There were, however going to be some very good exhibits. He had a list of those who had applied for space, as follows:—For electric batteries the Epstein Company had applied for 210ft.; for machines and appliances for producing electrical currents by mechanical power, the Electric Construction Company, of Wolverhampton, had applied for 1,088ft.; Messrs. Parsons and Co., Heaton Works, Newcastle-on-Tyne, had applied for 200ft.; Mr. Robert Ewing was going to give an exhibit of conduits of electric cables; Messrs. Ferranti had applied for 450ft., and were going to have a very large show of alternating-current motors; Mr. Lorrain, of the Strand, had applied for 110ft. to show an electric system of ventilation, clocks, &c.; there would be a very large and fine display of the General Electric Company, of Queen Victoria-street, which would be under the careful attention of their friend, Mr. Binswanger; Elmore's American and Canadian Patent Copper Depositing Company were going to show in actual operation a large exhibition of electro-deposited copper; the London Metallurgical Company had applied for 1,600ft., and were going to give an exhibition of silver plating; the Post Office was going to transfer almost bodily the exhibit which it had at the Crystal Palace; Messrs. Anders and Kottgen, Jeffery's-square, would have an exhibition of telegraphs, electric signals, and phonographs; the Phonopore Syndicate, of London-wall, would have an exhibit of phonopore telegraph apparatus; and in regard to their last section, the telephone and its appliances and phonographs, there would be exhibits by the Collier Audible Telephone Company, and the Homacoustic Speaking Tube Company. That was the official list of applications up to the present time, and he thought they would agree with him that it did not adequately represent the British electrical industry. His object in coming there that day was to ask for their assistance to get something more—to get some typical display of the modes of fitting up houses in the manner which was peculiar to English practice. His notion was that they should get together, if they possibly could, a syndicate, which would put up a suite of rooms, furnished by English furniture makers, decorated by English decorators, and fitted up by electric light engineers with all the latest and best appliances. If ten members could be induced to subscribe £200 each to show their own particular exhibits, the Royal Commission would come forward and take charge of the exhibit, and find funds to assist in carrying it out. That was the only suggestion he had to make. He might add that since their meeting they had received a circular dealing with the department of electricity at Chicago, which was asking English contractors to tender for the lighting of portions of the buildings, of which a certain part had been set aside for European houses.

Mr. EMILE GARCKE thought they were very much indebted to Mr. Preece for attending that meeting and giving them the information which he had done. He thought the suggestion which Mr. Preece had thrown out with a view to a combination on the part of several of the firms who had specialities was a very good one, and he would venture to suggest to the Committee for its consideration whether a circular could not be issued to the Section with a view of Mr. Preece's suggestion being adopted. He thought there were a number of firms in the country to whom the suggestion would be acceptable. On the other hand, there might be some difficulty as to firms representing heavy electrical engines, with regard to the difficulty they had of importing their machinery into America. He almost thought it would be better if Mr. Preece could suggest a smaller sum.

Mr. PREECE said that he had only mentioned £200 as an illustration.

Mr. BINSWANGER observed that in regard to drafting the circular to which reference had been made, the main question which presented itself to his mind should not be lost sight of, and should be mentioned in the circular, namely, that the Electrical Exhibition was not one which would be of use to them mainly for their trade with the United States, but with foreign countries. He believed the Chicago Exhibition would be the meeting place of a great many foreigners from South America, Canada, China, and the East, who would go there to see what was being done in connection with electricity. Most of those who went there would be interested in electrical matters, and from this point of view he believed that the Chicago Exhibition would be of the utmost importance to English electrical manufacturers. They were in the present moment in a peculiar state. Electrical engineering had passed the stage of experiment, and their resources for manufacturing were very great. They were all looking out for foreign markets in order to supply them, but foreign makers would be doing the same thing; and the race for these markets would be extremely keen. From this point of view the Chicago Exhibition would be of great importance. He did not speak at random, but from actual experience. For the last two or three years he had, through agencies, established a certain connection in the countries he had mentioned—especially in Canada, Mexico, Japan, and China; and he might inform the Chamber that he had received notices from almost every customer in those countries of their intention to visit the Chicago Exhibition. If, therefore, he were to abstain from exhibiting at Chicago, he

Digitized by Google

would very likely lose what he had already gained, and other people might come in where he had already established a trade. This seemed to him to be a very important point, and he was sure that English manufacturers could show up well in regard to either heavy or light engineering fittings, and could produce articles which would compare well with others. In England, thanks to the efforts of scientific men, fire insurance companies' inspectors, and consulting engineers, and an immense capital invested in electrical enterprise, the industry had been established on a sound and independent basis compared with what was seen in other countries. He believed that the industry would be helped by a comprehensive display of electrical goods at Chicago. As Mr. Preece had said, his (the speaker's) Company had decided to have an exhibit, but he did not believe that it would do them much good individually. He believed it would be better for his Company and other individual firms exhibiting if their *confrères* and other large manufacturers would exhibit comprehensively and together as one section.

The CHAIRMAN said he desired to ask Mr. Preece one question. The Chamber at one time ascertained that English exhibitors might put their English prices on all their goods as well as the prices at which they would be able to sell them at in America. A rumour, however, had reached him that this right had been countermanded, it being feared that if the two prices were shown at the same time the Americans would discover how much they had to pay through their protective system. He had heard, therefore, that the price at which the goods could be sold in England was not to be hown.

Mr. PREECE, in reply, stated that the executive of the Chicago Exhibition distinctly conceded to them the right to display on their goods the prices of the articles in England and America. A rumour got into the Press that this right was to be taken away. Sir Henry Wood thereupon went out to the United States with an *ultimatum* implying that if it were true that the concession mentioned was to be departed from, they would probably on this side take very strong measures indeed; but on the very day that Sir Henry Wood arrived in America, he telegraphed back saying that everything had been arranged most satisfactorily. The right in question, therefore, remained with them.

The SECRETARY, in reply to Mr. ERSKINE, said it was quite possible that if the Electrical Section decided to make a commencement towards carrying out Mr. Preece's suggestion, furniture, carpet and curtain manufacturers might be induced to take part in the Exhibition in connection with the suggestion that had been made.

Mr. MARSHALL (Gainsborough) said he thought it should be known that the steam-engine makers there had resolved to keep away from the Exhibition; and in connection with agricultural machinery, it had been unanimously decided that it would be disadvantageous to exhibit at Chicago.

The CHAIRMAN, after alluding to Mr. Garcke's suggestion as to the issue of a circular to the members of the Section, said that if sufficient members said they would exhibit, Mr. Murray could get the textile or furniture manufacturers to have a meeting to see what could be done in the direction which had been indicated. If this were regarded as a practical suggestion, the Chicago Committee would draft a circular and send it out. He thought it only right to say that some of the companies were in a difficulty. The companies who really supplied American patents in this country could hardly exhibit in Chicago.

It was eventually decided to issue the circular in question.

The CHAIRMAN then observed that what he was about to say was practically in the nature of a report of the Committee appointed at the annual meeting to deal with what seemed a very difficult question—namely, the London County Council rules with regard to overhead wires. They had had the advantage at the Committee of hearing the full evidence of the National Telephone Company, the New Telephone Company, and the Exchange Telegraph Company—in fact, of all interested in overhead wires, apart from wires for the purpose of electric lighting. When they entered on their task they felt that the rules in question were most restrictive of trade, and that they would really be seriously detrimental to the welfare of the electrical industry. They felt this to such an extent that after several meetings, at which they had had to work pretty hard, they prepared a petition to the Board of Trade. When he told the Section thatthe number of the bye-laws was 22 and that they objected to all of them except five, those present would see that the Committee had traversed the case of the London County Council pretty completely. He would like to state that the officials of the Chamber pushed forward the petition extremely well under great pressure. The Council of the Chamber were kind enough to give the Committee their full support, and the result was that the petition went on. A meeting of the officials of the Board of Trade was held with the representatives of these companies and of the London County Council. The result was that certain concessions were granted, but they did not go far enough. With the greatest possible courtesy, the President of the Board of Trade had allowed the Chamber to appear even after the inquiry had been held. Sir Vincent Barrington introduced the deputation on behalf of the Council, but under the circumstances it was a very small deputation. A good hearing was given to them, and the result had been to show, first, the willingness of the Board of Trade to listen to any sensible suggestion, and, secondly, the influence of the Chamber of Commerce; for, of the 22 rules to which he had referred, only one was unaltered. Upon this point he was bound to ask them not yet to give way. He would mention one or two instances showing the nature of the alterations which they had succeeded in obtaining. The Act under which the bye-laws were made was passed in 1891. This gave the County Council power to make bye-laws for the purpose of identification and regulation of the wires. The County Council demanded that before any wire was placed they should have a fortnight's notice. The companies naturally said that that was impossible; and eventually it was settled, thanks to the good sense of the Board of Trade, that instead of 14 days' notice beforehand, notice was to be given within one month after the wire had been put up. There were other very vexatious restrictions, and the view which he took, after meeting the Board of Trade officials, was that if the latter could be convinced that anything was really restrictive of trade, they were most willing to try and alter it. They had this difficulty: the Local Authorities were very powerful bodies, with whom they themselves could not compete with influence. Another rule—not very wise—was that the London County Council restricted themselves as to the length of span. It had been agreed that the companies should not have a greater length of span than 115 yards, but the London County Council had prohibited themselves from giving permission for more than 140 yards. That restriction had, however, been taken away. Another absurd thing was this: Some of the companies now had 70 and sometimes 140 wires on one pole, but they were to be restricted to 20. That had also been done away with. All that had been asked of them now was that whoever owned the poles should be responsible for the safety of the wires. There was a matter of very great importance in connection with this subject. The telephone industry had become a question of the greatest importance, and it must increase in importance, as they would gather when they bore in mind that during last year 160 millions of telephone messages were sent in this country, at a cost of little more than ½d. each; whereas only 66 millions of telegraph messages were sent, at a cost of about 7½d. The progress of the telephone had been so wonderful that they could understand the Postmaster-General calling out that his business had been damaged by it. The Board of Trade had met the telephone companies on every point except one; and he wanted to urge the Section to authorise the Committee to see if they could do something more in regard to this one point. They insisted still that the owners of the wire should be compelled to give permission to the Local Authority or the County Council, by themselves, their agents, or servants, at all reasonable times, to go on to the premises of any one to examine the wires and poles—the premises of anyone having given permission for a wayleave. He told Sir Courtenay Boyle that this was most restrictive to trade. A company might go and say to a man, "I want a wayleave here." The reply might be, "I shall be very glad to let you have it." Then the Company would say, "I am bound to tell you that at all reasonable hours the County Council inspector or servant might come on to your premises to inspect the wires." Upon that the Company would receive a refusal. While they fully recognised the great kindness and courtesy of the Board of Trade and the concessions they had already obtained, he asked them to authorise the Committee to take what steps they might think fit, with a view of getting some amelioration in the regulation referred to, so that the companies might endeavour to obtain permission for an inspection of the premises over which wayleaves had been erected; but that they should not be compelled to get this permission. The only reason for the bye-law was on the ground of public safety. They were all probably aware that before a Parliamentary committee two or three years ago it was established that out of 700,000 accidents in London only two could in any way be traced to telephone wires, which were then under no regulations. With respect, therefore, to the public safety, there could be no necessity for this upsetting of the theory of an Englishman's house being his castle by allowing the public authorities, "at any reasonable time," to go over his premises. He, therefore, asked them to let their committee still endeavour to work so as to get the alteration in question assented to.

Mr. BENNETT said he desired on behalf of his own company—and he believed he might also say on behalf of the National Telephone Company—to express their gratitude to Major Flood Page and the committee for the great trouble which they had taken. He thought that the telephone companies were now contented—since there must be bye-laws—with the existing bye-laws with the one exception that had been referred to. With the knowledge he had of telephone companies' business, he was sure that this bye-law would prove an insuperable obstacle to their business in many ways. It was very difficult in existing circumstances to obtain wayleaves, and

Digitized by Google

it was often utterly impossible to overcome the scruples of some persons about them. When the bye-law in question was added, he was sure that the wayleaves which they could at present obtain would be greatly reduced in number. If the committee considered it possible to do anything further, he thought that they ought to agree to the effort being made.

General WEBBER considered that there would be little difficulty in introducing into the wayleave agreement a clause which would permit an official of the Local Authority, in the interests of public and private safety, to inspect the attachment, accompanied by an officer of the company. He did not think they need have much to fear if they could agree with the Board of Trade that in future a carefully worded clause should be introduced into the wayleave agreement. With such a clause carefully worded he did not consider that wayleaves would be refused. As regarded the wayleaves which had already been obtained, the question was much more difficult. In such cases the Local Authority were, he thought, bound to show how the permission to inspect was to be obtained; and they had not shown how they were going to get over the difficulty.

The CHAIRMAN stated that their strongest point was, perhaps, one that he had not mentioned—that in the Bill which was eventually turned into the Act which gave the London County Council the bye-laws, they sought to obtain this power, but Parliament threw it out.

Mr. GARCKE thought that a clause could be introduced and made to appear as if it were in the interest of the householder, and that was a strong point in its favour if nothing better could be done; but if, as he understood, it was believed that there was some reasonable hope of getting what was wanted, it would not be advisable to put in the clause suggested by General Webber.

General WEBBER agreed that it would be better, of course, to have nothing said in the agreement about the matter.

Eventually it was decided to give the Committee the authority desired by them.

The CHAIRMAN stated that the next matter on the agenda was with reference to the action that had been taken by the Special Electrical Traction Committee. Those who were present were acquainted with all that the Committee knew, having heard read the proceedings of that Committee by way of report. They looked forward to the meeting to which he had referred—which was to be held in the following week—with very great interest, and if the arbitration of the Chamber could be used effectively, it would be, as he had already said, greatly beneficial to the industry. It was a very difficult question that they had to deal with, and one in connection with which the lawsuit that was now in progress in Leeds would only be the first of a large number. They had not yet approached the Post Office at all. They were only dealing with the companies that were now in dispute—the parties to the Leeds trial—practically, the National Telephone Company and the traction industry represented by the Leeds Tramway Company.

Mr. SINCLAIR said he believed it would be found that in most of the Bills that had been issued there was a saving clause to the Postmaster-General.

The CHAIRMAN afterwards stated that a member of the Section had given notice of his intention to draw the attention of the Committee to three matters—the standardising of machinery, uniformity of prices, and foreign competition. The member had given several reasons why he regarded these three points as of very great importance, but he had been called away to Manchester, and could not possibly be present that day. He thought they would all agree that these were matters which might be very well considered. About three years ago they tried the standardising of machinery, but they utterly failed to arrive at any conclusion, but that did not prove that the same result would follow now. Would the meeting approve the formation of a committee to deal with these three subjects?

Mr. GARCKE said he thought they ought first to hear what the member who had put them on the agenda had to say about them. They were all large and important questions, but they could be treated from so many points of view that he thought the Committee ought to have some practical instructions in regard to them.

It was ultimately decided to postpone the consideration of the matters, and it was subsequently decided to adjourn until October, the Section only to be called together in the interim in the event of there being anything important to communicate, the Committee holding their meetings in due course.

The CHAIRMAN, in reply to General WEBBER, said he thought they all felt that the question of electrical traction was very important, and when they met in the following week they would see what could be done to arrive at a settlement. With respect to the Leeds trial, a notion was abroad that litigation had gone so far that it was almost impossible to prevent its continuing; but on a review of all the circumstances it was felt that a meeting should be held beforehand, and that there might be a possibility of doing something.

The proceedings then terminated.

CORRESPONDENCE.

CARBON BRUSHES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Our experience in connection with train lighting dynamos on the Midland Railway may be of some value in this matter.

The dynamos are compensated for variation of speed by the automatic inverse variation of induction through the armature. The current from the dynamo varies from 60 amperes, for a light train, to 110 or 120 amperes for a heavy train. Under all these changing conditions, the lead of the brushes remains the same, merely reversing with reversal of direction of rotation. As would be presumed, the sparking with ordinary copper brushes was sometimes very considerable. Owing to the heavy jolting, the brushes have to press very heavily upon the commutator, and having to work on a commutator running in either direction, they must be radial, or nearly so. The only copper brushes that would behave well at all were gauze brushes, and, as an Irishman would add, they behaved abominably.

When we were at our wits' end, over two years ago, I tried some carbon brushes on a machine that was sparking badly; and it is merely the truth to say that since then the trouble has absolutely disappeared. All the commutators were turned up—(a true surface is necessary for carbon), and carbon brushes replaced the copper gauze. We never have to touch these commutators now. Doubtless, it would be preferable to have a considerably larger segment area for carbon brushes, but we had to do what we could with that which we had got.

They get rather hot with 100 amperes on for a long run, but the friction alone is answerable for 50 per cent. of the heating.

The only carbon in our stores on the morning I decided to try it was some hard gas carbon used for battery plates. Although we have tried several special makes since, nothing has suited the work nearly so well as this hard carbon—most of the other kinds wearing away too soon. There are two pairs of brushes on each machine, and the carbon is of the same size as the original gauze, viz., about $1\frac{1}{4}$in. by $\frac{1}{4}$in., and projects only $\frac{1}{4}$in. from the holder. The resistance of the contact is, I presume, the cause of their spark-annihilating property. We find it necessary to slightly lubricate the commutator.

Where a dynamo is under constant supervision and control, nothing, I venture to think, can beat gauze for brushes. But where a dynamo is subject to changes of speed, direction of rotation, induction, and current output, without supervision, carbon brushes are the only ones possible.—I am, &c.,

Midland Railway, Derby. J. SAYERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of July 8th a question is asked as to whether carbon brushes have been used for loads of 100 amperes. In America the great majority of dynamos for power and railway purposes use such brushes. One manufacturing company have in use considerably over one thousand dynamos, each of which has a capacity of over 120 amperes using carbon brushes, some of which machines have been in use for the past four years. The satisfaction that carbon has given has led the Thomson Houston Company to universally use carbon for all machines of 500 volts. In the bipolar type of machines two brushes are used in each holder, the area of contact being approximately $\frac{9}{16}$in. $\times$ $1\frac{7}{8}$in., the load of such machines being 120 amperes.

The largest machine using carbon brushes to the writer's knowledge has an output of 720 amperes, a cut of which is published in the *Electrical Engineer* of New York in the issue of June 29, page 655. This machine, together with a number of others, being constructed for the West End Street Railway Company of Boston for the new Power House. The quality of the carbon brush as well as the size of commutator are the principal considerations in designing such brushholders. The rise in temperature of a brush should not be greater than 100° Fahr. when running continuously on full load. However, such a rise is not often attained in practice, as the load on a power circuit is well known to be a fluctuating one. Where troubles have been met with the fault has not infrequently been found

Digitized by Google

to be in the contact between the brushholder and brush rather than between the brush and commutator.

There are numerous carbon brushes on the market good and otherwise. An ideal brush is the Carré manufactured in Paris; the carbon is of medium texture, free from grit, very little liable to break or chip, and very uniform. A soft brush on the one hand will smut a commutator, and a too hard brush will be liable to collapse or chip. The American imitation Carré brush leaves very little to be desired, and is only inferior to the French one in point perhaps of uniformity. Tangential carbon brushes are generally not very advisable. All carbon brushes should be copper-plated to insure good contact between the holder and brush, and for this reason the deposit should be tapered from a fine deposit near the point of contact to a thick coating near the butt. A carbon brush should have at least 1½ area of a copper brush for the same load.—Yours, &c.,

J. DOUGLAS DALLAS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to your remarks on the subject of carbon brushes, there seems to be no difficulty in the use of such for large currents, provided that the surface of contact between the brushes and the commutator is not less than 1 square inch for each 40 or 50 amperes. There is always a considerable heating of the commutator due to spark-suppression, since the energy which would otherwise be dissipated in the spark appears as heat at the surface of contact between brush and commutator. This heating, though injurious if excessive, does not destroy the surface of the commutator, as sparking would. There is no doubt that carbon brushes, either in the simple or the divided form, are most valuable where constant lead with variable load is necessary.—Yours, &c.,

Kensington, July 12, 1892. R. H. HOUSMAN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The following particulars may be of interest to those concerned in the application of carbon brushes.

For high-tension machines, especially when there is great variation in the external load, carbon brushes are most beneficial, and, indeed, necessary; but in dynamos in which heavy currents are forced through the brushes by a low E.M.F., the sectional area of the carbons would have to be such as would render their use impracticable. Apart from the consideration of resistance, 30 amperes per square inch of rubbing surface is a good working current density.

The most noticeable feature in the working of carbon brushes is the peculiar property they possess of not only reducing the sparking, but greatly neutralising its effect on the commutator, a phenomenon which, I believe, has not yet been accounted for. If a current density of 50 amperes per square inch be given, the carbon becomes incandescent at points, but the effect on the commutator is even then trifling compared with what would have been the case if similar conditions could have been set up with copper brushes.

In many cases the sparking in low-tension machines with copper brushes can be to a great extent prevented by employing a carbon tip at the end of the brush, where the sparking occurs.

I may remark that, although a good quality of carbon is essential, the manipulation of the brushes is of just as much, or even more, importance. As a case in point, I am informed by Mr. Chamen, of Messrs. Crompton and Co. (Limited), that one of their motors was made to run for 15 months, in constant work, with only one pair of carbon brushes, and that during that period the commutator showed no signs of wear, but kept a smooth polished surface, although the conditions of working necessitated the frequent stopping and restarting of the machine.—Yours, &c., N. G. THOMPSON.

ARC LAMPS ON 50-VOLT CIRCUITS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your extract of a forthcoming work by Messrs. Geipel and Kilgour, I observe it is stated that for working arc lamps in parallel there should be at least 60 volts available; but that 65 volts give better results, whilst 70 volts are used in some cases.

As such a statement, if allowed to pass unchallenged, may give rise to the erroneous impression that all arc lamps require at least 60 volts to give satisfactory results, I shall esteem it a favour if you will kindly give publicity to the fact that at Winchester House in Old Broad-street, there are several "Brockie-Pell" lamps, taking currents from six to 10 amperes, which have been working for some years in parallel with incandescent lamps *on a 50-volt circuit*. This pressure is kept very constant; and seeing that some of the lamps are used for illuminating the hall in the basement where companies' meetings are held daily, I think it is superfluous to say that the light leaves nothing to be desired. The arcs have in fact displaced a large number of incandescent lamps.

I may also mention that there are hundreds of the same type of lamp about the country giving the greatest satisfaction, which are working two in series on 100-volt incandescent circuits.—Yours, &c., JAMES BROCKIE.

Charlton, Kent, July 12, 1892.

TEST OF TWO 6,500-WATT WESTINGHOUSE TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the report of Dr. Hopkinson on our transformers, a copy of which has been sent to you, we have just received an intimation from Dr. Hopkinson that an error has occurred in the last paragraph but one, namely, the efficiency of the transformer at quarter load should read, "over 92 per cent.," instead of "84·7 per cent."

We should feel much obliged if you would kindly refer to this correction in your next issue.—Yours, &c.,

ARTHUR E. SCANES,
Secretary Westinghouse Electric Company.

[We are compelled to leave over an interesting letter on Electric Lighting in Switzerland.]

LEGAL INTELLIGENCE.

COURT OF APPEAL.

St. George Lane Fox v. Kensington and Knightsbridge Electric Lighting Company.

SUMMARY OF COUNSEL'S ARGUMENTS FOR DEFENDANTS.

We give below the Summaries of which both parties to the Appeal, now awaiting judgment, were permitted to make use. These Summaries are, of course, of a very disjointed character, but lose nothing by being compressed into paragraphs:—

FIRST.—*Lane Fox's Appeal.*

Defendants have now shown:—

1. Ayrton's curve breaks lamps at 110 volts.

2. 110 volts must be passed if (*a*) batteries to store; (*b*) batteries to regulate flicker; (*c*) batteries to be kept in health. Therefore some method to be adopted either to charge when lamps disconnected or with interposed cells and switches. Neither of these are Lane Fox, but all systems which have worked use one method or the other.

Lane Fox's case is not supported by the evidence, and amounts to this:—

Automatic Action by having Large Surface—(*a*) This is a fallacy, for chemical action is the reason for 110 volts being necessary, whatever capacity of cells; if surface increased, more current at same pressure required to do the work of storing up the energy; (*b*) Lane Fox was thinking of internal resistance of cell, not of chemical work to be done; (*c*) Batteries we use are large (Mr. Barrett describes them as enormous); (*d*) No sufficiently large battery ever thought of or made; (*e*) Prof. Perry suggested that same result could be obtained by using a small current with our cells; but all our experiments showed that this could not put in anything in the way of charge. Therefore patent would not work.

3. There is disconformity between provisional and complete:—(*a*) Use of batteries as reservoirs is not use for flicker regulators; (*b*) use of batteries as reservoirs is not use for dotting about to get over loss in leads at times of heavy load; (*c*) use of reservoirs is to add supply, and not to keep constancy; (*d*) the provisional use must at least be good invention, or there can be no development in complete.

4. Disclaimed invention is different from original complete invention.

5. *Insufficient Description.*—That the directions given for carrying out the invention are so vague as to be insufficient in the then state of knowledge. (*a*) Plates. "Very large conducting surface." (*β*) Even if switches and extra cells could be read in to the specification no directions how to use such novelties.

Digitized by Google

SECOND.—*Defendants' Cross Appeal.*

1. Patent invalid because earth (globe) or gas and water-pipes would not work:—(*a*) Because one method of "obtaining light by electricity" is the connecting of the negative pole of the lamp with the globe or gas and water-pipes;* (*b*) because earth an essential part of invention and part of merit. (I.) Because of saving in cost of return copper conductor. (II.) Because Lane Fox thought the globe was a vast reservoir of electricity, and the current once passed into the earth by an earth plate, and the dynamo connected by an earth plate, the necessary circuit would be formed with no resistance such as there would be in case of a return wire, corroborated by use of batteries dotted about to supply at different points, so as to enable station current to be always same quantity, and so prevent loss by resistance to heavy current; (*c*) earth means globe in specification on both views—*see* books; (*d*) earth means globe—*see* evidence; (*e*) earth would not work—*see* evidence; (*a*) would not take current; (*β*) corrosion of earth plate or pipes; (*γ*) uncommercial size of plate; (*δ*) removal of pipes for repairs, &c.; (*ε*) pipes are not continuous conductors. (A) Joints. (B) Chemical compound covering pipes; (*ζ*) resistance of earth plate or pipes will vary in proportion as soil is dry or damp. The pressure absorbed in overcoming resistance will have, therefore, to vary, which will necessitate pressure on mains varying.

Now, we have proved that patent invalid because earth (globe) or gas and water pipes would not work.

Subject matter: (*a*) Parallel distribution old; (*b*) batteries old; (*c*) combination old; (*d*) use of batteries as reservoirs, with a generating source of supply and consuming device old; (*e*) use of batteries as reservoirs to take up and provide supply obvious; (*f*) use of batteries for momentary flicker, *i.e.*, demand not in patent; (*g*) if it was, *old.*

Note.—Provisional use only to be considered in novelty and merit.

Note.—Plaintiff's object and invention (if any) is to dot batteries about system, so that dynamos at central station shall always be generating the same volume of current *whatever the demand*, the batteries supplying the extra current from each point of the mains, thereby having a fixed amount of pressure only absorbed in overcoming the resistance in leads to the flow of current, and by this means keeping the pressure at each particular point of the mains constant.

Infringement.—Defendants do not infringe because (*a*) Insulated return used by defendants not earth return; (*b*) use of secondary batteries entirely different. Vary certificate as to issues (*a*) earth; (*b*) subject matter; (*c*) use of secondary batteries entirely different.

I. Plaintiff's object and invention (if any) is to dot batteries about system so that dynamos at central station shall always be generating the same volume of current whatever the demand, the batteries supplying the extra current from each point of the mains. thereby having a fixed amount of pressure only absorbed† in overcoming the resistance in leads to the flow of current, and by this means keeping the pressure at each particular point of the mains constant. Whereas the defendants use the batteries simply as reservoirs to supply current from the central station. They rely upon their feeders to keep the current constant for delivery to the lamps all over the system at 100 volts, varying the size and length of their feeders carrying the current from their central station. That is, their feeders and not their batteries provide for loss through resistance in passing the current through mains.

II. Plaintiff alleges he uses batteries to regulate, defendants use them for storage to replace dynamos, their constancy of pressure is provided for by mechanical contrivances for regulation of engines.

Vary certificates as to issues.

ANSWER OF MR. LANE FOX TO "SUMMARY OF COUNSEL'S ARGUMENTS FOR DEFENDANTS."

Note.—Only a very little important evidence is here cited.

FIRST.—*Lane Fox's Appeal.*

1. It is not disputed that full battery has higher voltage than empty, whatever be the surface; neither is it disputed that if large currents are forced into and drawn out of a small battery, there may be considerable difference in the voltage of the charging and discharging curves. Such difference in voltage, however, means waste of energy. With charging and discharging currents of any amounts from large enough batteries there are only small differences in voltage between charge and discharge, even for considerable periods. Ayrton states that his curves are for the largest currents which the manufacturer thought it safe to use. Even Crompton (*see* question 7,407) published a statement long before this trial of very much smaller percentage differences of potential from complete charge to complete discharge than are shown on Ayrton's curves. Even in the most extreme case Ayrton's curves from point B in charge to point B′ in discharge only show a total change from 110 to 98, or less than 6 per cent. up and 6 per cent. down, taking the normal voltage of the mains and lamps at 104. Mr. Justice Smith admits that this range of 6 per cent. above and below normal may be used in practice (*see* lines 32 and 33, page 782). Mr. Justice Smith seems to have thought that the lamp must be a 100-volt lamp; whereas lamps of various voltages are used, and obviously a 104-volt lamp would not be injured at 110, according to Mr. Justice Smith's judgment.

2. If it is necessary to charge 50 cells above 110 volts, let normal pressure of mains and lamps be 110 or thereabouts; or use fewer cells if normal pressure of mains 100 volts. (*a*) Sufficient storage depends on size of batteries: but even taking Ayrton's curves, about three-quarters, full storage capacity of cell is obtained without passing 110 volts, and within 6 per cent. up and down range. (*b*) Flicker is regulated at all points of charge and discharge of cells. (*c*) Planté's batteries did not deteriorate; and he expressly states that bubbling, *i.e.*, high voltage, is undesirable—(Bramwell, 4,373), (Forbes, 3,927 to 3,931), (Barrett, 3,316 and 2,265). Lane Fox system can be worked without switches; also switches were obvious additions (Barrett's evidence and Lane Fox, 1,985).

Lane Fox case is supported by evidence.

(*a*) Chemical action is cause of static voltage (*i.e.*, voltage on "open circuit" when battery is neither charging nor discharging) whether full or empty. Why do defendants refer to this as applying only to 110 volts? This is most misleading, as chemical action applies to all static voltages of a cell whether full or empty. Moreover, point B on Ayrton's curve (110 volts) is considerably above the static voltage at that moment (Crompton, 7,531 to 7,532). The second part of (*a*) is in plaintiff's favour, for it also means that the same current at less pressure is required, as battery has larger surface, which is his contention; (*b*) he was thinking of both; (*c*) this is a purely relative matter; the defendants' batteries cost only a very small percentage of whole capital; (*d*) *see* Drake (9,097); (*e*) *re* Crompton's cell—*see* remarks, page 674, lines 35 to 45. Crompton's results untrustworthy; contradicted by King's and Drake's curves. *See* also Crompton, question 7,407.

3. There is no disconformity. (*a*) Use of word "reservoir" implies regulation; (*b*) mere amplification of provisional; (*c*) use to keep constancy implies use as a reservoir; (*d*) provisional use was invention, as even the system of lighting (which is part of the combination) was new. It is, however, the combination which is relied upon.

4. This objection is based on theory that regulation is different from keeping constancy of pressure. No justification for this theory.

5. Contradicted by evidence. No evidence in support. Bramwell, 4,108 to 4,110, and *see* Plimpton Skate, case 3, Chancery Division, page 570, as to size of working parts. Switches well known—*see* Bramwell.

SECOND.—*Defendants' Cross Appeal.*

1. Use of term "earth" in specification suggested to every electrician; in 1878 the necessity for a suitable return, however, obtained. This probably points to corrosion, and is a purely commercial question. (*a*) Note to (*a*) misleading and fallacious; (*b*) and (*c*) earth used in description and figures in specification for sake of clearness and simplicity. Very difficult to draw Fig. 5, showing return by cable, without using two colours. Earth is not an essential part of invention (*see* Bramwell); (*d*) contradicted by all plaintiff's witnesses and see books; (*e*) even if earth is held to mean soil it would work in small installation; (*a*), (*β*), (*γ*), (*δ*), (*ε*), (*ζ*), *see* Hopkinson, questions 4,956 to 4,960.

Subject Matter.—General Note by Lane Fox.

The idea of supplying electricity to incandescent lamps in parallel, as gas and water are supplied, was new in 1878 (Perry, 53 and 735-738; Lane Fox, 914-938; Barrett, 3,225-3,236; Thompson, 2,841-2,845). To carry out this idea it was necessary to have constancy of pressure (we use word "pressure," not used before 1878, because the analogy with gas and water was not known), and everything described in specification is for this purpose. This is the essence of patent combined with the system; he, therefore, uses secondary batteries for balancing or regulation, and even now this is important (Miller,). Nothing like the system of lighting itself, or the use of a resorvoir for balancing or regulating in combination with such a system, was known to Clark and Achard, or was anticipated by anybody (*see* Perry, 39-41; Clark and Achard's reservoir, Perry, 120; Lane Fox's reservoir, Perry, 119; Perry, 289-311; and all plaintiff's witnesses. *See* also Clark's specification, page 3, lines 16-21; also page 7, lines 5-10).

Answers to Defendants' Arguments.

(*a*) System of distribution, net-work of mains at nearly constant pressure and high-resistance lamps new; (*b*) admitted; (*c*) combination quite new. (*d*) and (*e*) *See* Perry, questions 39 to 42. Analogy, air-gun old user, fire-engine air-vessel new user. (*f*) Incorrect. Included even in provisional by use of word "reservoir" and context (Perry, 91 and 98). (*g*) Absolutely no evidence.

Note.—Absolutely denied (Crompton, 7,224 to 7,226).

Infringement.—(*a*) Defendants use an equivalent return well-known in 1878. (*b*) Contradicted by evidence.—*See* Bramwell, questions 4,486-4,491. *See* Hopkinson, question 5,297.

I. Plaintiff intended to keep same pressure all over mains—*see* Crompton, questions 7,224-7,226. Feeder mains a simple amplification or improvement of Lane Fox system. This also applies to switches.

II. Contradicted by evidence—*see* Crompton, question 7,392; Miller question 8,055 to 8,063.

* We do not know which way the flow is; and the direction as to return, as it is called in this, the very first system of electric lighting, is most necessary, witness telegraphy and arc lighting, the only other electrical applications known, for there earth could be used.

† If current increased more pressure would be lost in overcoming the resistance of mains.

Stone v. Metropolitan Electric Supply Company.

Recently, at the Bloomsbury County Court, his Honour Judge Bacon heard the case of "Stone v. the Metropolitan Electric Supply Company," which was a claim for one week's wages in lieu of notice. The plaintiff is a stoker, and said that he was engaged by Mr. Allborough, the superintendent of the Company, on trial, and subsequently taken on the staff at 30s. 4d. per week of seven watches. He was a union man, and as there was some trouble with union men on the works, he was discharged along with others on Monday, May 2nd. He was only paid for one watch, although he asked for a week's wages in lieu of notice. He had since been unable to get employment in London owing to the "row," and he

Digitized by Google

now brought this action as much to vindicate his character as to recover the money due to him.

The defence was that it was customary for companies to dismiss stokers on a watch notice, or to pay them for a watch.

The Judge said that he thought that in such work as this electric supply, where anything like a strike or sudden caprice on the part of the men might cause injury to employers, it was not unreasonable that the men should be liable to dismissal at the termination of one period for which they receive their wages. He (the learned judge) was satisfied that this man was employed by the eight hours, and was not entitled to a week's notice.

Judgment for the defendant company.

TRADE NOTES AND NOTICES.

TENDERS INVITED.—Firms wishing to tender for the supply of mains and fittings in a large block of City offices are invited to communicate in writing to Major-General C. E. Webber, Portland House, Basinghall-street, E.C., by Monday, the 18th inst.

——— Tenders will be received up to 12 noon on the 25th instant by Messrs. Milnes and France, architects, 99, Swan-arcade, Bradford, for the works required in the erection of the buildings for the Leeds Electricity Works.

TENDERS RECEIVED.—Five tenders have been received by the Electrical Committee of the Bristol Town Council for the supply of the condensing plant for the electric light installation, and have been referred to Mr. Preece, the consulting electrician, for his advice thereon.

——— The Public Lighting Committee of the Basingstoke Town Council have reported that they have received a tender for lighting the town by electricity, but that the amount was too high for them to recommend its acceptance. The gas company had made a considerably-reduced offer for lighting the streets, which was agreed to by the Council.

PLANT FOR SALE.—Messrs. Wheatley Kirk, Price and Goulty set out in our advertising columns particulars of high-class engines, boilers and other plant which they have for sale. These include several complete installations for arc and incandescent lighting. Particulars and lists can be obtained on application to Messrs. Wheatley Kirk, Price and Goulty, 52, Queen Victoria-street, E.C.

SALES BY AUCTION.—Messrs. Brodie, Timbs, and Baker, auctioneers, 68, Finsbury-pavement, E.C., announce in our advertisement columns that, by order of the liquidator, they will sell by auction, on the premises, 37, Tabernacle-street, E.C., on Tuesday next, the 19th inst., the valuable stock and machinery belonging to the Vaughan-Sherrin Electrical Engineering Company, Limited (in voluntary liquidation), including an Otto gas engine, an Elwell-Parker compound dynamo, &c.

——— Messrs. H. N. Newton and Co., auctioneers, 67 and 69, Chancery-lane, W.C., will sell by auction, at the Phœnix Works, Boleyn-road, Dalston, on Thursday next, the 21st inst., a quantity of nearly new and valuable machinery, including a 12 H.P. vertical engine, an 8 H.P. and a 3 H.P. gas engine, screw-cutting lathes, drilling machines, &c. Further particulars appear in our advertisement columns.

WOODHOUSE AND RAWSON UNITED (LIMITED).—In reference to the report that this firm have removed their head offices from Queen Victoria-street, we are able to state that these head offices will remain at the old address, 88, Queen Victoria-street, E.C., but that for the future the firm are storing the bulk of their specialities at Hammersmith.

THE ELECTRICAL COMPANY (LIMITED).—The business heretofore carried on under the name of Keys' Electric Company (Limited) has been reconstructed, and will be carried on in future under the above title. Mr. F. T. Eggers is the liquidator of the old Company.

EPSTEIN ACCUMULATORS.—We are informed that the Birmingham Central Tramways Company have just placed an order for 600 Epstein cells with the Midlands branch of Woodhouse and Rawson United (Limited) for use upon their electric car route.

MESSRS. DRAKE AND GORHAM.—This firm have received the contract for the work in connection with the additional installation at the Harrow Schools, and also for an installation at Hartsdown, near Margate, and a water-power installation for the Duke of Montrose at Buchanan Castle.

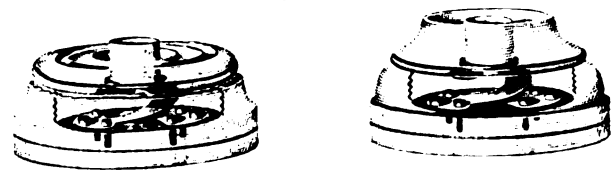
MR. A. A. C. SWINTON.—"Chesters," Northumberland, is to be electric lighted under the auspices of Mr. Swinton, the installation consisting of about 330 incandescent lights.

GENERAL ELECTRIC POWER AND TRACTION COMPANY (LIMITED).—This Company have received instructions from the War Office to erect a five-ton electric travelling crane at Woolwich Arsenal. The firm have also just added another dynamo to the extensive plant at Messrs. Locke and Co.'s, St. John's Colliery, Normanton. This machine was started on Saturday last.

PROPOSED ELECTRIC LIGHTING FOR LEITH DOCKS.—The Leith Dock Commissioners, at their last meeting, had submitted to them part of a report regarding the cost of the introduction of electric light into the docks, from which it was gathered that the estimated cost of engines and other necessary plant would be £8,000, and the annual maintenance of the light £2,000. The Clerk stated that the annual cost of gas was about £2,197.

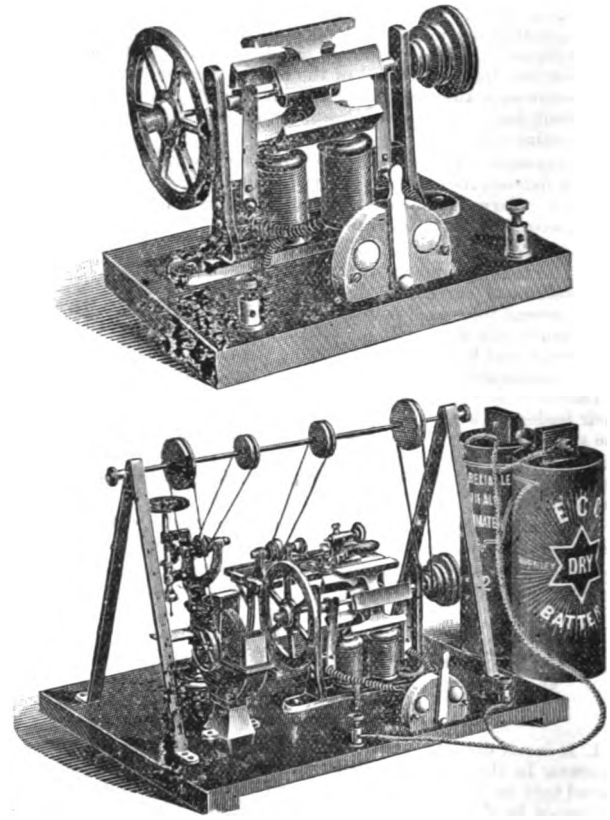
MUIR, MAVOR AND COULSON (LIMITED).—A meeting of the shareholders in this Company (in voluntary liquidation) will be held at 139, St. Vincent-street, Glasgow, on August 10th, at 12 noon, to receive an account of the winding up.

GENERAL ELECTRIC COMPANY.—This Company send us specimens of a new porcelain electric bell-push, which we herewith illustrate. The cover screws on with a good thread, and the plate and spring are screwed on to the back by a pair of brass screws, the holes



New Porcelain Bell Push.

being tapped in the porcelain, but not coming through. A third screw on each plate is provided for the wire. The bell-push is most substantial, and an improvement on many of the usual patterns with wood or ebonite backs. The Company also send for



A New Toy Workshop.

our inspection a toy workshop, driven by an electric motor, for which they expect a considerable demand at the coming Christmas-tide. Some idea of the working of this novelty will be gathered from the illustrations.

HERBERT W. HOOPER AND CO.—The following are among the creditors of Herbert W. Hooper, carrying on business as an electrical engineer, at 17, Prince's-street, Hanover-square, who, as reported in last week's *Electrician*, has filed a deed of assignment:—

Acme Electrical Works, London	£19
Day and Co., London	17
Edison and Swan United Electric Light Co. (Limited), London	30
General Electrical Company (Limited), London	12
Girdlestone, Tatham and Co., London	15
Glover (W. T.) and Co., London	21
Godfrey, Giles and Co., London	36
India-rubber, Gutta-percha and Telegraph Works Co. (Limited), London	14
Munro's Electrical Manufacturing Co. (Limited), Glasgow	33
Poole and White, London	24
Tautz, E., London	67

COMPANIES' MEETINGS & REPORTS.

National Telephone Company (Limited).

The twelfth ordinary general meeting of this Company was held yesterday (Thursday) at the City Terminus Hotel, Cannon-street, under the presidency of Mr. James Staats Forbes.

The SECRETARY (Mr. Albert Anns) having read the notice calling the meeting, the report of the Directors was taken as read.

The CHAIRMAN, in opening the proceedings, referred with great regret to the loss which the Company had sustained by the sudden death of the late Chairman, Mr. F. R. Leyland, to whose devotion to the interests of the Company he warmly testified. Passing to the report, he stated that the income for the past year had been £463,741, which was £32,600 more than in the previous year. Their subscribers paid in advance, and also for intervals of time not limited by a particular year. A man, for instance, might come in as a yearly subscriber on January 1st, whereas the Company's business year ended on April 30th; and, therefore, as they took the subscription in advance for 12 months, obviously only a portion of the amount could be attributed to the part of the year to which it applied. A table at the end of the report gave an abstract of the accounts for the past three years, showing full details as to the earnings, and how the receipts were applied. All the details were given in this abstract, and he thought it would be most useful to continue this information from year to year, so that the shareholders might be enabled to see at a glance what the financial aspect of the Company was in relation to income and profits. Concurrently with the increase in the income of the year there had been a considerable increase in their expenditure upon capital account, and the net income had become chargeable to the extent of about £18,000 on account of this additional outlay. If they came to consider the increase he had mentioned of £32,628 upon so large a figure of income as £431,000, it did not seem too brilliant, as it was only 7 per cent. on the whole, but certain points in connection with this increase had to be borne in mind. For instance, they had had to anticipate certain things, and looking forward they had thought that the time had arrived, as the period of the patent expired, for relieving the subscribers of some portion of the charge which they had hitherto paid. The present was the first complete year in which the alteration thus made applied, and the reduced rates amounted to no less than £55,000, assuming that they had kept the same number of subscribers. Other considerations, which he detailed, brought up the amount to £65,500, by which their revenue had been reduced in the past year compared with the previous year. It was all very well to say, "Reduce the amount you charge for subscriptions," but it was to be remembered that the amount of the reduction would all come out of one pocket—that of the shareholders. Having had more work to do their expenses had also increased, having amounted to £236,252, or £36,768 more. In face of these circumstances, of course, there would naturally be a diminished net revenue, and the decrease had amounted to £7,797. Notwithstanding the drawbacks he had mentioned, they had had an increase in their gross income, and the number of their subscribers had increased under the influence, more or less, of the reduction they had made in their charges. The increase in their business had been 20 per cent., and the cost of conducting the business had been higher by 18 per cent. They would, therefore, see that the expenses had only kept pace with the increase in the number of their subscribers. It should be remembered that the royalties which they paid to the Post Office were on their gross receipts, and not on their net income. Out of the divisible balance, after providing for interest on debenture stock, an interim dividend for the first-half year had been paid at the rate of 6 per cent. per annum on the preference shares and 5 per cent. per annum on the ordinary shares; and out of the balance, notwithstanding the operation of the circumstances he had mentioned, there remained enough to pay a further dividend for the past half-year at the rate of 6 per cent. per annum on the preference shares and 7 per cent. per annum on the ordinary shares, making the distribution on the latter 6 per cent. for the year. There then remained a balance of about £15,000, and they proposed to carry to reserve account £10,000 of this amount in addition to £1,127 placed to reserve during the year from premium account. This would bring up the reserve account to £104,627, which was a very substantial figure. He thought they would see from what he had said that they had been very wisely discounting the future with a view to discouraging competition. They had emerged from protection into the more healthy atmosphere of free trade, and their object had been to take care that their service was made not only efficient but that their charges should be so moderate in relation to the value of the work done by them that their customers should not be tempted by competition. They had added to capital account during the year £320,991, the bulk of which had been spent on attaching subscribers, and as regarded £95,000 of the amount, it represented their outlay on laying trunk lines. Their business was made up of two things—their local service in a given area, where they invited subscribers to the local exchange or exchanges, and the means of connecting those areas—London, for instance—with more distant places, say, Manchester or Liverpool. Their through wires were enormously valuable to them, because they might be made to pay by themselves a reasonable dividend, in addition to which they acted as an inducement in attracting local subscribers, who might not in many cases be disposed to pay for merely local exchanges. As he had said, the increase in their lines had been 20 per cent., which they would see represented a considerable number of new subscribers, and the cost of installing the lines had been £250,000. The net revenue had slightly diminished, having been charged with its increased burdens. The balance sheet contained two entries relating to the purchase of the telephone business of the Sheffield Telephone Exchange and Electric Light Company, £40,619, and the purchase of the undertaking of the Caledonian Telephone Company, £4,500. These were items accruing due in respect of the purchase of these businesses when all the details and preliminaries connected with the agreement were determined. These matters had to be settled before they parted with their money, but he might state that they had acquired on very advantageous terms the two businesses he had mentioned. Paragraph 8 was a somewhat important one, as it opened up a very large question, and threw on the Board a most serious responsibility. The Company were universal licensees—that was, they had the privilege within the whole of the United Kingdom of laying down lines, opening exchanges, fixing rates, and conducting their business in their own fashion. That was a policy that was initiated by a man who had considerable claims to statesmanship—the late Mr. Fawcett, when he was Postmaster-General—in contradistinction to an earlier policy, which was to limit their lines and powers. That policy was tried and found wanting. The expansion of telephones throughout the kingdom was impossible under this state of things, and Mr. Fawcett was wise enough to see that, as the result of experience. He accordingly broke down all bounds and left the Company free, and they had gone on for several years spending their money and incurring risks upon the faith of that contract—that they should be free to do these things. There was one blemish in the matter—that was, that all they did was on sufferance. They had no legal status, no legal powers, and he thought it marvellous that their enterprise had been built up absolutely on sufferance. They had no legal rights in regard to putting up any wires or posts, and yet they had done so; but this state of things had resulted in this—that the telephone in England had not advanced in relative user or in relative perfection with its advance in other countries where the conditions were different. If they had had legal powers to do all those things which must be done in order to make an efficient service they would have done it long ago. What he had stated ought to be borne in mind by those who went about talking of the relative iniquities of their poor Company, and compared it with institutions where the Government had everything in their hands and could do as they liked, their Company, as he had already stated, having absolutely no legal powers whatever. They had been knocking at the door of Parliament for several years, to ask them to let the Company do what the subscribers and the public had complained that they did not do—give an efficient service and expand their business; but the Post Office would not let them in. This was a question affecting the public interest. The Post Office bought the monopoly of the telegraphs at a price which made them very uncomfortable, and the policy of the Post Office with reference to telephones until lately had appeared to be to leave them to struggle as best they could in the prosecution of their business, but by no means to help them. He did not complain of the Post Office. It had a business, purchased at an enormous price, and at the risk of the taxpayers, not of shareholders, and the Post Office were bound to protect their revenue. Protecting their revenue, however, meant not giving too many facilities to the telephone, because, as sure as morning followed night, the telephone was going to supersede the telegraph to a very great extent. This was illustrated by one or two figures. The Post Office was a Government department, with all the prestige of the State. They could do things which a private company could not do, and the constitution of the public was so singular that they would take at the hands of a State department what would be regarded as insufferable at the hands of a private monopoly. With all the advantages possessed by the Post Office, however, he found from their last book year that they transmitted, having been in existence a good many years, 66 millions of telegrams. They had popularised their service by 6d. telegrams. They had, however, wiped out their revenue entirely, but the State did not pay for this. They had no shareholders but the taxpayers. Their 66 million of messages cost the people who sent them something very nearly approaching 9d. each. Their Company, however, carried on a very reasonable approximate estimate—not at 6d., the message being limited to 12 words, of which very often the address and signature meant 6 words—but communications, so to speak, oral to the extent of 160 millions, and at a price approximating to 1½d. each. These communications, too, did not include the addresses, because they found out the addresses themselves, and put the people in communication with each other for nothing. He would like to ask them to measure the difference by this standard of the two services. Supposing the 160 millions of oral communications had been charged according to their value merely as measured by the words that passed, he supposed that the average of the communications would mean, not 12 words, but 40 or 50. If they worked that calculation out at ½d. a word, they would see what they arrived at; but he had put it rather high at 1½d. And this was going on, and the State had suddenly awakened to the position. The Company had been howling because they could get no powers. A Committee in 1884 heard the whole story, and they reported that it was a matter of such grave public importance that every restriction should be taken from it, and that it should be assisted. Nothing, however, had been done in the matter until now. Mr. Goschen was a very able man, and, no doubt, as Chancellor of the Exchequer, had had his eye on the Post Office telegraphs for the purposes of revenue. The Post Office authorities had had the Company's Bill before them, and the Company received notice that it was not to be proceeded with. Still, it did what it was intended to do—it brought the question to a head; and the Government had determined on a policy under which it was proposed that all the trunk lines used for inter-town telephonic communication should become the property of, and be worked by, the State, the exchanges and local service remaining in the hands of the Companies for the term of their present licences. This policy reversed to some extent the policy of Mr. Fawcett. It set up barriers—that was to say, the Companies or the Company as the licensees were to be entitled to areas to be determined by the

Digitized by Google

Government to carry on its business of exchanges, but it could not break bounds except through the Government instrument—the trunk wires. A man in London, therefore, could not communicate outside a particular area; but what the particular area was to be was not defined. They knew what their present area was, but they did not know what it was to be. It seemed, therefore, to come to this, that the policy to which he had alluded as inaugurated by Mr. Fawcett was reversed, and they were to be restricted to certain areas, and without any powers—or, at all events, with powers so shady that they did not seem to be worth much. This appeared to him to be retrogression. The Treasury Minute which had been published explained the policy, which was very curious. It was a hit at monopolists. It said, what was perfectly true, that their Company, having had to begin the business, having had to take all the risks of its imperfections as a new discovery, and all the risks of applying it without legal powers—having invested their money in this state of things, they were now to go back to a limited area. Of course, they had very valuable connections through their trunk wires to London with hundreds of towns which could intercommunicate with each other. The proposal was that they should surrender this intercommunication and hand it over to the State In virtue of that surrender they were to be left in certain areas and to have certain privileges given to them in the way of conveniences of some value for their subscribers; but they considered that that alone as an equivalent was not very much. The surrender of their trunk lines deprived them of just those advantages which the Treasury Minute declared to be a monopoly in the hands of a private company. They would probably become a monopoly, because, having covered England with trunk wires, it would be very difficult for other people to follow them. This was an accurate argument out of the mouth of the Post Office. The carriage of letters, however, was a monopoly, and certainly the telegraphs were a monopoly; and the telephone could not be separated from the telegraph. They could run together, they might bring one to help the other; but the proposal of the Government was a half-and-half measure. It brought in a dual control, it would not facilitate either the promptitude or the simplicity—he was not sure that it would promote the economy—of the telephone. The proper thing to do was for the Government to acquire the thing; but they did not do this. The shareholders would see what a delicate and difficult position the Board was in. They might agree with the Post Office to surrender their present constitution, which gave them universal power as far as they could exercise it, and they might accept limited powers; but they did more or less put themselves in the hands of the Post Office. It was true that they were free not to agree; but then, said the Post Office, "If you do not agree, some one else will. We will promote people who will, and will afford them the means of trunk communication from one end of the kingdom to the other, and competition with you will then be a very easy matter." Upon this and other grounds they had made up their minds that they ought to agree with the Post Office, because, as licensees of the Post Office, their relations were so dependent on that department in many ways that mere prudence and loyalty would involve their doing everything they could to make this policy succeed. But, of course, it was at present "Hamlet" without the chief character. The Company wanted to know what the consideration was to be. The surrender of the trunk wires was a condition *sine qua non*. This meant some important consideration. The cost of the trunk wires was not an equivalent, because if they surrendered these wires at the price which had been paid for them, they would not only give up the trunk wires, but also the 19 years' enjoyment of the profit which the lines were put up to earn, and which they would earn, and earn in growing quantities. The matter depended on their getting fair terms, and they were now in negotiation with the Post Office. At the present moment, however, a little complication had arisen as to the future. It was easy to negotiate with responsible heads when they were there, but when they were not, one must wait and see what turned up. This was a matter of the gravest public moment. If the telephone service of the country was to be conducted efficiently and economically it must be in the hands of one or the other. It was as much a monopoly in the nature of it as the transmission of telegrams or the conveyance of letters was; and although competition was a favourite thing and always took with the public, the latter were so blind that they would not see that combination followed competition as surely as night followed day, particularly in a business of this sort, where the areas were narrow, the difficulties great, and the multiplication of capital and control meant, not simplicity and economy, but competition and wastefulness. The Government, therefore, ought to do one thing or the other. They ought to recognise that the telephone was in the nature of it a monopoly, and commit the conduct of the business to licensees under proper Government restraint, or they ought to do it themselves; and he ventured to predict that their attempt to do a big thing in a weak-kneed manner would not succeed. Notwithstanding that, however, the Company would not be absolved from doing all in their power to make it succeed. It would be unfair to throw upon the Directors such an immense responsibility as to determine the whole future of the Company upon an agreement the result of which no man could absolutely clearly predict. One might have some idea as to what might happen, but it would be more or less a jump in the dark. The business of the Company was increasing. They had added to it certain subsidiary lines—among others the important centre of Sheffield, where there was not only existing competition, but the threat of further competition at the hands of new people. They had bought this enterprise up at a price which, in reference to the secured income at present and the security from disadvantage in the future, was a very moderate sum indeed. Sheffield was a great centre of industry, and the Company's nets were spread wide, their strength depending on having in every centre in their subscribers friends as well as customers; and this meant that in these centres gentlemen of position and knowledge should be with them who could excite the sympathy of the subscribers and keep in touch with them. In view of this important consideration, Mr. George Franklin had been appointed a Director, he being a gentleman who was well known in Sheffield. As their business was getting very large and complicated, and its ramifications were extending from day to day, they had appointed Mr. William E. L. Gaine as general manager, he being a gentleman who had had practical opportunities of conducting a great organisation and carrying out a business more or less analogous to their own. He concluded by moving the adoption of the report and the payment of the dividends recommended.

Colonel R. RAYNSFORD JACKSON having seconded the motion, a brief discussion followed.

The CHAIRMAN, in reply to questions, stated that their wires, poles, machinery, &c., were always changing their character, and what they did was to maintain their structure out of revenue. If a pole or any of their machinery became bad it was replaced at the cost of revenue, and in that sense the depreciation of the undertaking was maintained out of its profits. Everyone knew that boards of directors, with members living in London, Glasgow, Edinburgh, Sheffield, and a dozen other places could not sit permanently, and, therefore, they were obliged to delegate the work of the Company to what was called the Executive Committee, to which, under the Articles of Association, the Directors, in their discretion, might award further remuneration, and they had done so to the extent of £5,000 a year. There were, however, 12 Directors. If this was objected to it had better be settled at that meeting. Not one of the Directors considered that he was paid too much, and not one of them was there for the fees which he received. They were among the largest shareholders of the Company. He had heard of the New Telephone Company, but as far as he was able to ascertain, it was a good deal in the air. He hoped that the New Company would be wise in time, and not invest their money in fruitless competition. Their reserve fund was invested in the business of the Company. If that were not so they would have to raise additional capital to the same amount, and he supposed that in the present condition of things they would not be able to raise much money under 4½ per cent. If their business was to progress as it ought to do they would want a great deal more capital. He had omitted to state that the Directors had in their minds the creation of about £1,000.000 of Five per Cent. Stock for the purpose of buying up the undertaking of the Western Counties and South Wales Telephone Company, and for paying for the other businesses.

The resolution was carried unanimously; and the retiring Directors and auditors having been re-elected, the proceedings terminated in the usual manner.

Paris and New York Cable Company.

A meeting of the Paris and New York Cable Company was held on Tuesday afternoon last, at which more than 21,000 shares were represented. American shareholders took no part in the proceedings. The Chairman announced the resignation of the entire Board; whereupon a discussion, lasting over two hours, took place. One of the principal shareholders laid particular stress upon the necessity for the French Company to avoid, in the interests of State secrets, all participation of the American element. A new Board of seven members was elected, representing French interests alone, as follows:—MM. Bruyère Dellorier, Sutterlin, G. Vian (of the old Board), and De Carrère, Salmon Halphen, Bernard, and Pestel (new Directors).

Edison and Swan United Electric Light Company (Limited).

The following is the report of the Directors of this Company to be presented at the ninth annual meeting, to be held at the Cannon-street Hotel, on Tuesday next, the 19th inst., at 12 noon:—

The business of the Company for the year ending June 30th last has resulted in a credit balance of £74,810. 16s. 7d. Of this amount £30,271. 15s. 11d. has been already distributed as an interim payment on the "A" shares for the first six months of the year in respect to dividend and arrears. The Directors recommend a further distribution of a dividend on the "A" shares of the Company, of 5s. 8¾d. per share on the 89,261 ordinary shares, £3 paid; of 9s. 6½d. per share on the 5,000 £5 fully-paid shares allotted to the Edison Electric Light Company (Limited); and of 8s. 10¾d. per share on the 12,139 £5 fully-paid shares allotted to the Swan United Electric Light Company (Limited), free of income tax, being, with the interim dividend paid on February 22, 1892, 7 per cent. in respect of the year ending June 30, 1892; 7 per cent. in payment of arrears of cumulative preferential dividend for the year ending June 30, 1887; and of 4 per cent. in respect of the year ending June 30, 1888; all to be distributed in accordance with the provisions of Clause 87 of the Articles of Association, which will absorb £33,354. 4s. 9d., leaving £11,184. 15s. 11d., which the Directors have carried to the reserve fund, in accordance with Clause 89 of the Articles of Association.

The Directors are glad to say that their electrical fittings business is prospering. The amount received as royalty from those who hold licences for manufacturing holders and sockets for incandescent lamps is satisfactory, and is likely to increase year by year.

The Directors desire to record their sense of the loss which the Company have sustained by the death of Mr. F. R. Leyland. The Directors have elected Major Samuel Flood Page, who had been secretary and manager of the Company since 1883, to fill the place on the Board. The Earl of Lichfield and Mr. Ernest Villiers retire by rotation from the Board, and offer themselves for re-election as Directors. Messrs. Welton, Jones and Co., auditors, also retire, and offer themselves for re-election.

Chili Telephone Company (Limited).

An ordinary general meeting of this Company was held at Winchester House, London, E.C., on the 8th inst., "for the purpose of receiving the report of the Directors and statement of accounts, the election of a Director, the appointment of an auditor, and for the transaction of the ordinary business of the Company." Colonel R. Raynsford Jackson presided.

Mr. EDMUND PETLEY (the Secretary) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN: Gentlemen, the report we have to present to you is conspicuous for two leading features—one which we may consider adverse and the other beneficial, leading us to hope for better things in the future. The adverse feature is that the profits are less than they were in the previous year. The net profit in sterling for the last year was £6,067, or £7,622 less than the profit for the previous year. You all know why the profits are less than they were. A fierce revolutionary war in Chili has disorganised every interest there, and ours among the rest; and one of the consequences has been a wholesale destruction of lines and poles and works, causing an increase in the expenses involved in carrying on our business. Although the profits are so much less than for the year 1890-1, the receipts in Chili are very little less, and that leads us to hope that we shall have a rapid development of our business. The receipts in 1890-1 were $387,110, while in the year under consideration they were $378,830, being a difference of $8,280, so that the effect of the revolutionary war was to reduce the receipts in Chili by 2½ per cent. only. That was a great change from the previous year, when the increase of gross revenue was 47 per cent., but there were indications that for the remaining portion of the current year their revenue would progress at the old rate. The new revenue secured in April was $7,962, and in May, $7,690, or pretty much the rate of increase which prevailed in 1890-1. This leads us to hope that we are to a great extent passed the disorganisation in Chili arising from the revolution, and that from this time forth we may expect to increase our revenue and to make our position secure. Although the difference of the receipts in dollars in Chili was only $8,280, the expenses were $76,120 more. Then, again, the dollar was worth 19½d. as against 24d. in the previous year, which also militated against the profits as reckoned in sterling. Our position has been altered in some important respects. You are aware that according to the report issued last year we were obliged to conduct our business through our manager, who also required and received the appointment of the West Coast Telephone Company. It was stated also that a minority of the shareholders of the vending company opposed the sanction by the Court of the transfer of the West Coast Company's enterprise to this Company. That opposition has since been withdrawn, and the title of the Chili Telephone Company to their property having been duly and legally registered, we have got over all the difficulties I have referred to. On the favourable side is this further important fact: an arrangement has been entered into with the Government of Chili for the supply of a telephonic service in Chili for ten years, and similar arrangements have been entered into with the authorities of Santiago and Valparaiso. The latter will enable us to erect poles in these two cities, and will give us the support of the municipal authorities in the two largest cities in Chili, strengthening our position, and assisting the development of the Company. Our revenue has now reached $400,000 up to the end of May. This leads the Directors to think that the time has come when they may safely regard the earnings of the Company as legitimately the property of the shareholders in the form of dividend. There is a proposal in the report as to a method of meeting what the shareholders had a right to expect in this particular. All our earnings have been spent in Chili, and treated as capital. That has been done because this is not the time to ask the public to subscribe for shares in any enterprise connected with South America, and if we were to issue capital with the view of putting the accounts between revenue and capital right we should raise our new money on very unfavourable terms. We have thought it expedient that we should issue deferred warrants payable when capital is in hand for the earnings of the past two years, giving an option to the shareholders, any time between now and March 31st next year, of converting their warrants into shares of the Company. The Directors hope that as a rule the shareholders will so deal with these warrants, because the effect would be to increase the capital of the Company in an easy manner to the extent of £20,000. I beg to move that the report and statement of the accounts be received and adopted, and I may add that carrying this resolution does not bind you to the deferred warrant dividend proposal, for which a formal resolution will afterwards be proposed. The first resolution which I beg to move is—

"*That the Report of the Directors, with the statement of accounts to March 31, 1892, now presented to this meeting, be approved and adopted.*"

Mr. THOMAS GREENWOOD seconded the motion.

Dr. J. R. LEESON said that he would like to ask a question in regard to paragraph No. 8 of the report, which stated—"As the bulk of the increased expenditure has been caused by the revolution, a claim has been made against the Government, of which $115,000 remains unpaid. No part of this sum has been treated as an asset in the Company's accounts; whatever may be hereafter received from the Chilian Government will be credited to future revenue." He would like to know as to this claim which had been made how much it was in the first instance and whether any arrangement had been arrived at with the Chilian Government as to payment of the remainder.

Mr. W. J. DEY said that he would like to ask in reference to the deferred warrants when they would be payable, and also whether they would bear interest until they were paid.

The CHAIRMAN: Are there any other questions, because I will answer them all together?

No further questions were asked.

The CHAIRMAN said that in reply to the question of Dr. Leeson as to the $115,000 referred to in paragraph No. 8 in the report, the matter was still under negotiation, and they had made a claim to that extent, but how far that claim would be successful and acknowledged by the Government they were not in a position at the present time to state. With regard to the other question that had been raised, he would like to draw attention to the fact that in the report for the year 1890-91 the accounts were credited with the sum of $62,000 which had been received from the Government, and they had received subsequently about $30,000 more, which had been credited to the revenue of the accounts presented to the shareholders for the last year. As to the question of Mr. Dey, in respect to the deferred warrants, they would not carry interest; but up to the 31st March next they could be converted into shares of the Company. After that time the warrants that were not so converted would be paid when the circumstances of the Company allowed of their payment, but he hoped that the majority of the shareholders would convert their certificates into shares of the Company. If there were no further questions he would put the resolution.

The motion was unanimously carried.

The CHAIRMAN said that the next question that they had to consider was the resolution in regard to the payment of dividend, and he begged to propose—

"*That a dividend of 10s. a share, free of income tax, be declared upon the ordinary shares of the Company, not to be payable immediately, but to be represented by certificates, which may be exchanged on presentation before the 31st March, 1893, for an equal amount of the Company's shares (fully paid, £5 each) entitled to dividend from 1st April, 1892, and that such certificates as may not be so exchanged shall be paid in cash after due notice, at such time as, in the opinion of the Board, the state of the Company's finances admit of such payment being made.*"

Mr. THOMAS GREENWOOD, in seconding the motion, said that of course these deferred warrants would bear no interest whatever, although the shares into which they could be converted would be credited for dividend. It was therefore distinctly to the interest of the shareholders to make that change and to convert the warrants into shares, as otherwise they would be without dividend and without any interest upon their money. By this means £20,000 of capital would be raised which otherwise would have to be obtained in another way, and their shares not being worth par any issue would not be very much in favour with the public, and therefore the shareholders would be manifestly helping the enterprise themselves by bringing in these deferred warrants and converting them into shares of the Company. With regard to the conversion of the deferred warrants into shares he was desirous of pointing out that this conversion must take place and the deferred warrants must be presented before March 31, 1893, or otherwise the privilege of converting the warrants into shares would be gone. As to the point that had been raised in regard to the date for the payment of the deferred warrants in cash which were not converted into shares, they could not possibly at present fix the time because they could not be paid until they had earnings sufficient to meet them, and, as the shareholders were aware, the present cash resources of the Company were low, and they had not got the wherewithal to pay these warrants at the present time. Of course some shareholders might prefer to sell their warrants rather than to hold them or to convert them into shares; he knew that such an impression had got about, and if they so desired it was at their option to do so, and get a smaller dividend in cash by the sale. He had taken the trouble of giving these particulars in regard to the proposals in respect to these deferred warrants, because, although there were so few shareholders attending at the meeting that day, a report of the proceedings would, no doubt, be sent to the shareholders who were absent, and they would thereby have the means of receiving information which they would probably desire, but which, otherwise, they perhaps would be unable to obtain. He commended the acceptance of the resolution to the shareholders.

The resolution was put and unanimously carried.

The CHAIRMAN stated that the next business was the re-election of the retiring Director, Mr. Frank W. Jones, who was a very valuable member of the Board, and who had previously been connected with the West Coast Telephone Company. Mr. Jones took a very great interest in the affairs of the Chili Company and had experience of the country, and he (the Chairman) hoped they would re-elect him. He formally moved—

"*That Mr. Frank W. Jones be and he is hereby re-elected a Director of this Company.*"

The Hon. F. E. ALLSOPP seconded the motion, which was unanimously carried.

The CHAIRMAN stated the next business rested with the shareholders. It was the re-appointment of auditors.

Dr. LEESON proposed the re-election of the retiring auditor, Mr. T. A. Welton.

Dr. WALTER JOHNSON seconded the motion, which was carried.

On the motion of Dr. LEESON, seconded by Mr. DEY, a cordial vote of thanks was accorded to the Chairman and Directors of the Company.

The CHAIRMAN in returning thanks expressed a hope that they would ultimately bring the Company to a success which would be satisfactory to the shareholders.

The proceedings then terminated.

Western Counties and South Wales Telephone Company (Limited).

An extraordinary general meeting of the shareholders of this Company was held at the Grand Hotel, Broad-street, Bristol, on Friday, under the presidency of Mr. George Nash, for the purpose of confirming the resolu-

Digitized by Google

tions passed at the extraordinary general meeting held on the 21st ult., approving the transfer of the business and property of the Company to the National Telephone Company (Limited). (See *The Electrician*. June 24th).

The CHAIRMAN formally moved that the resolutions be confirmed, and this was seconded by Mr. MARK WHITWILL; and after some remarks by Mr. G. WHITE, criticising the action of the Directors in carrying out the transfer, the resolution was put to the meeting and carried.

Telegraph Construction and Maintenance Company (Limited).

In accordance with the resolution of the general meeting of February 28, 1871, a half-yearly general meeting of this Company was held on Tuesday at the offices, 38, Old Broad street; Sir George Elliot, Bart., presiding.

Mr. WILLIAM SHUTER having read the notice calling the meeting,

The CHAIRMAN said: Gentlemen, this meeting, as you are all aware, is not convened for the purpose of making any kind of investigation into the accounts of the Company, but is rather a kind of recognition of the goodwill existing between the shareholders and the Directors. I remember many years ago when the meeting was founded, and that is the view we took of it. I will just briefly read to you a few things which have happened since we last met. During the past half-year we have carried out a contract with the Western and Brazilian Company by laying about 770 miles of cable along the coast of Brazil (between Santos and Chuy), and have made various repairs in that Company's cables on the same coast. We have laid a cable nearly 300 miles in length along the eastern coast of Sumatra for the Dutch Government (through the Eastern Extension Company); we have made several repairs in the German Government cable between Emden, on the river Ems, and Valentia, in Ireland: and we have likewise made repairs in the Direct United States Company's cable on the banks off the coast of Nova Scotia. Our general business—which is business outside cable laying—has been fairly good compared with the similar period of last year. I do not know that there is anything of a commercial or controversial character that arises beyond what I have stated. We meet merely, as I said before, rather to feel that we are going on quietly, doing our best, and also in the belief which I hold that the Directors have the entire confidence of the shareholders. The Directors, too, have great confidence in the concern itself as being *bonâ fide* in the interests of the shareholders. We never have any resolution at this meeting, which is a kind of *réunion* among ourselves each half-year. That is the whole of the business, unless any shareholder has any question to ask.

Mr. OXENHAM: May I ask one question—that is, what is the nature of the outside business that the Company is doing, and which you mentioned?

Mr. SHUTER: We have a large business in gutta-percha at our works in Wharf-road, City-road.

Mr. OXENHAM: I have not often attended these meetings, so I was not exactly aware what the other business was.

The CHAIRMAN: It is a very fine business, and there are large premises for it.

Mr. HEWAT: It only remains for the shareholders, I think, to propose a vote of thanks to you for the information you have given us. I hope the year's accounts will end satisfactorily.

The motion was unanimously agreed to.

The CHAIRMAN: The fewer questions that are asked and the greater the confidence between the shareholders and the Directors the better it will be for the interests of the Company. It is our strength that there should be no misrepresentations in regard to our affairs.

The proceedings then terminated.

London Tramways Company (Limited).

At the general meeting of this Company held last Monday at the offices in Camberwell New-road (Mr. David P. Sellar presiding),

Mr. HENRY C. CLEMENTS advocated the adoption of electric cars in substitution for horse cars. He stated that he had had numerous communications with shareholders, and all of those who had written to him approved the proposed change. He had just heard that the use of electric cars on the North Metropolitan Tramways was not a success, but he did not believe it. He had ridden on them several times, and had made inquiries both from the drivers and conductors, who had told him that they were perfectly safe. Moreover, there was the City and South London Company, and was not the use of electric cars on that system a success? ("No, no.") Had they discontinued them, then?

The CHAIRMAN: They run in a hole; we run in the streets.

Mr. CLEMENTS, continuing, said that he believed that ten different railway companies had lately applied for Acts of Parliament, and in all their Bills they had asked for authority to use other mechanical power. He maintained that the use of electricity on tramway cars was not a failure, and he proposed a resolution setting out—

"*That the time had arrived when it would be much to the interest of the shareholders that there should be no unnecessary delay in substituting electric cars for horse cars.*"

On behalf of the 110 shareholders who had sent him their proxies, he suggested that they should try one part of the system first—say, the Peckham line, and see how the arrangement worked. He did not advocate that electric cars should be run as an experiment, because there was no experiment about it; but he wanted the accounts to be kept separate, and for the matter to be in the hands of half-a dozen of the shareholders, to see that everything was carried out properly. He knew of a gas engine at the present time which would make electricity sufficient for any two of the Company's cars to run continuously, and the expense of this gas engine was 18s. a week. Many of the shareholders approved of his proposal. He had heard from two electrical companies—one of which supplied the North Metropolitan Company—that the cost of electricity, with everything connected with it, would be such that in 1891 this Company would have saved £100,000 from having had electric power instead of horse-power.

The CHAIRMAN, in reply, stated that the Glasgow Tramways were to be taken over by the Glasgow Corporation in two or three years. The Corporation had stated that the cheapest form of traction was electricity, which they endeavoured to obtain, but subsequently they decided to continue the use of horses. The whole of the London Tramways Company's tramways would have to be relaid before they could run electric cars; and they would also have to go to Parliament for powers to use electricity. In America there was not an electrical tramway running through the means of an accumulator. The Company (he said) ran one car down the Peckham-road every minute, and if they used electricity, and one of the cars got out of order, the whole of the line would be blocked.

The resolution was seconded, but was declared lost.

Eastern Telegraph Company (Limited).

The following is the report of the Directors for the half-year ended 31st March last, to be presented to the fortieth half-yearly ordinary general meeting, to be held at Winchester House, E.C., on Friday next, the 22nd inst., at one o'clock:—

The revenue for the six months ended the 31st March amounted to £382,207. 11s. 4d., from which are deducted £105,820. 13s. for the ordinary expenses and £53,515. 5s. 1d. for expenditure relating to repairs and renewals of cables, &c., during the half-year. After providing £2,970. 17s. 6d. for income tax, there remains a balance of £219,900. 15s. 9d., to which is added £57,509. 7s. 1d., brought from the preceding half-year, making a total available balance of £277,410. 2s. 10d. From this amount there have been paid:—

	£	s.	d.
Interest on Debentures and Debenture Stock	22,274	13	3
Dividend on Preference Shares.....	20,474	2	0
An interim dividend of 1¼ per cent. on the ordinary shares	50,000	0	0
	£98,748	15	3

Leaving a balance of £178,661. 7s. 7d., from which £68,000 has been carried to general reserve.

The Directors now recommend the declaration of a final dividend for the year ended March 31, 1892, of 2s. 6d. per share and a bonus of 3s. per share, amounting together to £110,000, both payable on the 22nd inst., free of income-tax, and making, with the three previous payments on account, a total distribution of 13s. per share, or 6½ per cent. for the year on the ordinary shares. The balance of £661. 7s. 7d. shown at the foot of the revenue account is proposed to be carried forward to the next half-year.

The revenue includes £32,791. 12s. dividends and bonus for the half-year upon the Company's investments in the Eastern and South African, the Black Sea, the Direct Spanish, and the African Direct Telegraph Companies.

The shareholders having at the last general meeting approved the principle of establishing a staff pension fund, your Directors have had the details worked out by experienced actuaries, and a scheme will be submitted to the meeting for dealing with the matter, together with a formal resolution empowering the Directors to carry out the necessary arrangements.

Electrical Power Storage Company (Limited).

The following is the report of the Directors of this Company, to be presented to the shareholders at the third ordinary general meeting, to be held on Wednesday, July 20th, at 4, Great Winchester-street, London, E.C., at 12:30 p.m.:—

The gross profit and other sums receivable amount to £37,045. 12s. 2d. The Directors have made provision for maintenance of buildings, plant and tools, and depreciation, by writing off the sum of £1,401. 6s. 1d. The net profit, after payment of general expenses, management, &c., is £5,763 11s. 9d., out of which the Directors propose to pay a dividend of 6 per cent. on the paid-up capital of the Company. This will absorb £5,017. 4s. 2d., and the remainder, viz., £746. 7s. 7d., the Directors propose to carry forward to next account.

The Directors have during the past year completed the necessary arrangements for changing the name of the Company from the Foreign and Colonial Electrical Power Storage Company (Limited) to Electrical Power Storage Company (Limited), thus restoring to the Company the prestige of the old E.P.S. name.

During the past twelve months the Company has acquired a lease of the storage battery manufacturing business previously carried on by the Electric Construction Corporation at Millwall and Wolverhampton, and included in this lease is the use of the plant, machinery, and, for a period of three years, of the stock existing at Millwall, where the business is now carried on.

The accounts have been made up to May 31, 1892, as at that date the lease of the manufacturing business from the Electric Construction Corporation (Limited) had been in existence twelve months. The shareholders will note with satisfaction from the profit above mentioned that the business of the Company exhibits marked vitality.

The patents of the Company have been upheld abroad by legal decisions, which should have a beneficial effect upon the general business of the Company.

The utility of secondary batteries for the work of central electric lighting stations, and the absolute necessity of such apparatus in private light-

Digitized by Google

ing installations being now generally admitted, the Directors are devoting attention to the commercial application of the secondary battery to electric traction. Very considerable success has attended the use of the Company's batteries for electric launch work. Some thousands of cells are, and have been, in use for this purpose during the past five years. Much activity exists among the various engineers, who are endeavouring to develop commercial methods of electrically propelling tramcars, omnibuses, and other vehicles, and the Company is in a position to profit by the successful result of their labours.

The Directors are pleased to report that at the Crystal Palace Electrical Exhibition, 1892, the Company received the only gold medal for storage batteries.

The retiring Directors are Mr. Frederick Green and Mr. James Pender, who, being eligible, offer themselves for re-election. The auditors, Messrs. Broads, Paterson and Co., also offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES DIRECTORY AND HANDBOOK, 1892, *pages 308-322, &c., &c.*]

HENRY WIGGIN AND CO. (LIMITED).—Registered with a capital of £160,000, in £10 shares, to carry into effect an agreement for the acquisition of the business now carried on by Messrs. Henry Wiggin and Co., of Birmingham and Smethwick, and of Thomas Adkins and Co., of Smethwick, as refiners of nickel and cobalt, manufacturers of German silver, red lead, &c , and as metallurgists and manufacturing chemists, and to carry on and extend the said businesses in all their respective branches.

HEPBURN AND GALE (LIMITED).—Registered with a capital of £60,000, in £10 shares, to adopt and carry into effect an agreement, made June 8th, between Hepburn and Gale (Limited), of the one part, and W. A. Posnett, on behalf of this Company, of the other part ; generally to carry on business as tanners, curriers, leather merchants, manufacturers of eather belting, hose pipes, and all leather articles for mechanical purposes

J. C. HOWELL (LIMITED).—This Company was registered on the 9th inst., with a capital of £25,000, in £5 shares. The objects are to acquire all or part of the businesses, goodwill, machinery, rights, privileges, and other property of Mr. John Charles Howell, of New Dock, Llanelly, and of 24, Queen Victoria-street, London, E.C., electric light engineer ; to acquire any letters patent relating to inventions for the production and supply of light, heat, or power, by means of electricity, magnetism, or other power ; to generate, accumulate, and distribute electricity, and to contract for the lighting and heating by electricity of any public or private property. The subscribers are (each with one share) John C. Howell, Llanelly (electric light engineer); W. M. Meredith, Dorking (engineer); H. C. Cornish, Llanelly ; T. H. Lewin, Parkhurst, Dorking ; Percy C. Scrutton, 24, Queen Victoria-street, E.C. (electrical engineer) ; H. de B. Porter, The Hollies, Finchley, N. ; W. Eacott, 29, Powell-road, Clapton, N.E. The number of Directors is not to be less than three nor more than seven, the first being John C. Howell and W. M. Meredith, who are Managing Directors for a period of five years from the date of the incorporation of the Company.

JAMES SIMPSON AND CO. (LIMITED).—Registered with a capital of £250,000, in £10 shares, to acquire the undertaking, property, and assets, of James Simpson and Co. (Limited), registered on December 19, 1885, and to carry on at the engine works, Grosvenor-road, Pimlico, and elsewhere, the business of manufacturing engineers, mechanical and electrical engineers, machine and engineering tool makers, boiler makers, iron founders, brass founders, metal workers, &c.

LITHANODE AND GENERAL ELECTRIC COMPANY (LIMITED).—This Company was registered on the 8th inst, with a capital of £100,000, in £1 shares. The objects are to adopt and carry into effect an agreement to be made between the Mining and General Electric Lamp Company (Limited) and its liquidator of the one part and this Company of the other part ; to carry on the business of an electric, gas and other light company ; to construct, lay down, establish, fix and carry out all necessary mains, reservoirs, cables, wires, lines, accumulators, lamps, machinery and works ; to manufacture, generate, accumulate, distribute and supply electricity, gas, &c. ; and to carry on business as electricians, mechanical engineers, gas engineers, lamp manufacturers, manufacturing chemists, contractors for public and private works, suppliers of electricity and manufacturers of electrical and scientific apparatus. The subscribers are (with one share each) J. E. Huxtable, 14, St. Helen's-place, E.C. ; C. H. B. Ince, 102, Alexandra-road, South Hampstead ; L. Mossop, B.A., 7, Camball-road, Putney ; C. R. Pearson, 2, Balfour-terrace, High-road, Leytonstone ; J. E. Wood, 10, Placquett road, East Dulwich, S.E. ; A. C. Crane, 3, Wood-lane, Highgate, N. ; J. A Gedge, 14, Abbeville-road South, Clapham Park, S.W. The number of Directors is not to be less than three nor more than nine, the first to be appointed by the above-named subscribers.

RICHMOND (SURREY) ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—This Company was registered on the 8th inst., with a capital of £50,000, in £5 shares. The objects are to carry out the terms of the Richmond (Surrey) Electric Lighting Order, 1883, in so far as they may be capable of being carried out in accordance with and subject to the provisions of a contract dated December 8th, 1891, and made between the Corporation of the Borough of Richmond of the one part, and Latimer Clark, Muirhead and Co. (Limited) of the other part ; to enter into and carry into effect the agreement with the said Latimer Clark, Muirhead and Co (Limited), mentioned in Clause 3 of the Articles of Association of the Company, whereby the benefit of the said contract of December 8, 1891, is agreed to be assigned to the Company, and to carry on throughout the Municipal Borough of Richmond and any further extensions thereof, the business of an electric light and power company for any public and private purposes, as defined by the Electric Lighting Act, 1882, and subject to the provisions of the said Act and the Electric Lighting Act, 1888. The subscribers are (with one share each) William E. Grigsby, LL.D., B.C.L., M.A., 7, King's Bench-walk, Temple ; Sir Edward Hertslet, C.B., Bellevue House, Richmond ; Douglas B. Hall Heywood, Maidenhead, Berks ; Robert L. Kidd, Kewfoot-road, Richmond ; J. Soares, Richmond ; Francis B. Alston, 69, Eccleston-square ; Edward C. Curtis, 15, Cranley-place, S.W. The number of Directors is not to be less than three nor more than seven, the first to be appointed by the above-named signatories.

HERSEY BROTHERS (LIMITED).—This Company was registered on July 8, 1892, with a capital of £5,000, divided into 250 £8 per cent. preference and 250 ordinary shares of £10 each, to acquire, take over as a going concern, and carry on the business of a gas, water, electric, and ventilation engineer, now carried on by George W. Hersey, under the style or firm of Hersey Brothers, at 70, Berners-street, Oxford-street, W.

THOMAS PIGGOTT AND CO. (LIMITED).—Capital £90,000, in £10 shares, to acquire, take over as a going concern, and carry on the business of gas, water, mechanical, and electrical engineers, steel, iron, and brass founders, metal workers, millwrights, &c., belonging to, and carried on by, Messrs. Thomas Piggott and Co.

CALLENDER'S BITUMEN, TELEGRAPH, AND WATERPROOF COMPANY (LIMITED).—The annual return of this Company, made up to May 31st, was filed on June 10th. The Company was registered on April 19, 1882, with a capital of £40,000, in £10 shares, and in 1891 the capital was raised to £80,000 by the addition of 4,000 new shares of £10 each. At the time of making up, 6,316 shares were taken up, of which 3,000 had been issued as fully paid, as part payment of the purchase consideration ; upon the remaining 3,316 the full amount had been called, resulting in the payment of £29,371, and leaving £3,789 in arrears.

CUTTRISS, WALLIS AND COMPANY (LIMITED).—The annual return of this Company, made up to June 16th, was filed on the 22nd. The nominal capital is £10,000, in £5 shares. 736 shares have been taken up, of which 420 have been issued as fully paid. Upon the remaining 316 shares a call of £4 per share has been paid.

ELECTRIC AND GENERAL INVESTMENT COMPANY (LIMITED).—The annual return of this Company, made up to June 23rd, was filed on the 8th inst. Out of a nominal capital of £200,000, divided into 39,900 ordinary and 100 founders' shares of £5 each, 20,000 ordinary and 100 founders' shares have been taken up, Upon the ordinary shares a call of £1 per share has been made, and upon the founders' shares the full amount has been called, resulting in the payment of £20,500.

ELMORE'S GERMAN AND AUSTRO-HUNGARIAN METAL COMPANY (LIMITED).—The annual return of this Company, made up to June 23rd, was filed on the 1st inst. Out of a nominal capital of £200,000 in £2 shares, 75,000 shares have been taken up, of which 25,000 have been issued as fully-paid as part payment of the purchase consideration. Upon the remaining 50,000 shares the full amount has been called, resulting in the payment of £95,395. 5s., and leaving £4,604. 15s. unpaid.

PIONEER TELEPHONE COMPANY (LIMITED).—The statutory return of this Company, made up to June 25th, was filed on the 4th inst. 6,000 of the 10,000 £10 shares have been taken up, and the full amount called. The calls paid amount to £59,910, and unpaid to £90.

CITY NOTES, &c.

BABCOCK AND WILCOX (LIMITED).—The Stock Exchange Committee have appointed this day (Friday) the special settling day in this Company's Six per Cent. Cumulative Preference Shares Nos. 3,334 to 10,000, and Ordinary Shares Nos. 4,667 to 14,000, and have ordered these securities to be quoted in the official list.

CALLS DUE.—*July 15th :* £2. 10s. final on SOUTH AMERICAN CABLE COMPANY'S 20,000 £10 shares.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended July 10th were £733, as against £692 for the corresponding period of last year, being an increase of £41. The total receipts to date, from January 1st last amount to £21,210, against £19,917 in the corresponding period of 1891, being an increase of £1,293.

DIVIDENDS DUE.—*July 23rd :* EASTERN TELEGRAPH COMPANY, LIMITED, 2s. 6d. per share for quarter and 3s. bonus. *July 31st :* EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY, LIMITED, 7 per cent. for year ending June 30th, 7 per cent. arrears to June 30, 1887, and 4 per cent. arrears to June 30, 1888. *Not dated :* NATIONAL TELEPHONE COMPANY, LIMITED, 7 per cent. for year ended April 30th. *July 22nd :* WEST AFRICAN TELEGRAPH COMPANY, LIMITED, 5s. per share. *Not dated :* WESTERN UNION TELEGRAPH COMPANY, dividend for quarter at the rate of 5 per cent. per annum.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended July 8, 1892, after deducting 17 per

Digitized by Google

cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,790.

CRICKET.—EASTERN TELEGRAPH COMPANY (LIMITED) v. KENNETH ANDERSON AND COMPANY.—This annual match was played on Saturday last at Neasden, and resulted in a victory for the Easterns. K. A. and Co. went in first, and put together 64 runs. The Easterns were more successful, and made 166 runs. Mr. Prosser, the Eastern Company's superintendent at Perim, contributed 66, winning the bat presented for the highest score. With only 35 minutes' play, K. A. and Co. started their second innings, and put together 100 runs without the loss of a wicket, when time was called. The ball for the best bowling average went to Mr. Burke (Eastern). Score:—

K. A. AND CO.—F. Spencer, b J. G. Macmillan, 26, not out, 26; G. C. Hawes, c Hardie, b Burke, 0; — Beaton, b Burke, 14; A. Jack (Capt.), c Draper, b Macmillan, 9, not out, 74; H. Gurney, b Burke, 1; Kenneth Anderson, b Burke, 5; A. Gardner, b J. G. Macmillan, 1; Stuart Anderson, not out, 4; J. White, c Wells, b Burke, 0; Kenneth Anderson, Jun., c Hardie, b Burke, 0; J. Strudwick, run out, 0; extras, 4; totals, 64, and (for no wicket) 100.

EASTERNS.—H. O. Wells, b A. Jack, 9; A. W. Prosser, lbw b Gardner, 56; G. C. Jack, b A. Jack, 45; A. R. Hardie, b A. Jack, 0; George Draper (Capt.), run out, 0; J. G. Macmillan, b A. Jack, 31; H. J. Burke, c and b A. Jack, 16; A. Penny, not out, 5; T. Richardson, st Beaton, b A. Jack, 0; A. G. Macmillan, b Kenneth Anderson, 0; A. W. Donaldson, c A. Jack, b Kenneth Anderson, 0; extras, 6; total, 166.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 740.—Vol. XXIX. FRIDAY, JULY 22, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

The Medical Battery Company (under which title the Harness "electropathic" belts are made) has attempted to recover five guineas from an unfortunate man who submitted himself to them for treatment. Medical evidence showed that he was suffering from hernia; but a furniture salesman employed by the Battery Company to look after such patients did not recognise it, and "fitted" him with a belt which chafed the skin and caused excruciating pain. Mr. Gatehouse, to whom we are indebted for the report of which an abstract will be found in another column, gave evidence about the non-electrical properties of the belt. In the result, the Company's application was dismissed, and the counter-claim for return of part payment was allowed with costs. It is a pity the case did not turn upon the "electrical properties" of this so-called "electric" belt. We yet hope to learn that the subject of these wretched impostures may lead to a successful Treasury prosecution.

It is worthy of note that although the wiring at the Crystal Palace Electrical Exhibition was of a temporary character, and unusually high voltages were employed, there was not a single alarm of fire, a result of which Mr. Heaphy is naturally proud.

The Corporation of Brighton have issued a circular containing a number of useful suggestions and hints about the use of electric light. The prices are a good deal less than might have been expected, the charge per Board of Trade unit being 7d.; and the cost of wiring, "inclusive of simple fittings," is put at 20s. to 30s. per lamp. The Corporation does not undertake wiring, but recommends local firms, and offers the advice and assistance of their engineer. The importance of sufficient wiring is insisted upon; and it is recommended that a drop of only 1 per cent. should be allowed. The uniformity of pressure maintained by the Corporation is alluded to several times in this circular; and we hope that they have got over the difficulty of the insufficient size of their mains, which was threatened some little time ago. It is easy to read between the lines of this pamphlet a reference or two to a rival supply; and we find a claim that "arc lamps supplied from the Corporation continuous-current mains produce nearly 100 per cent. more light than those from the alternating-current system for the same amount of electricity charged;" and "the electricity consumed by them can be exactly measured, which cannot be done by any known meter of the lamps which are supplied by alternating currents."

At the same time that they resolved to spend some £26,000 on electric lighting, the Corporation of Blackpool, as will be seen in our Notes column, also decided to put the post of supervisor of this large expenditure up to tender; that is to say, the Town Clerk was directed to advertise for a resident electrical engineer, "applicants to state amount of salary required." We have no doubt that this step will result in an immediate relief of the rates, if only the cast-iron rule of the acceptance of the lowest tender be adhered to. Electrical engineers are a glut in the market, and it is by no means difficult to imagine some of them going so far as to offer the Corporation a good round sum in hard cash for the privilege of gaining a little practical experience. The title of the municipal electrical engineer has up to the present been more imposing than his emoluments, and if the example set by the Blackpool Corporation should prove contagious, the salary curve will rapidly tend to zero, and may ultimately become a negative quantity.

The eagle eye of Colonel Makins, of the Gas Light and Coke Company, has discovered an ambiguous sentence in the remarks appended to the tables relating to electrical supply, which appeared in our issue of July 8th; and our contemporary, the *Journal of Gas Lighting*, which had published the information without detecting the ambiguity, has consequently been moved to attack us somewhat in the age-of-chivalry-is-past vein.

Endeavouring to arrive at a rough approximation of the output of the Gas Light and Coke Company, as compared with that of *all* the statutory electricity supply companies in London, we concluded as follows:—

"The output of the Gas Light and Coke Company for the half-year ending December 31, 1891, was 10,000,000,000 cubic feet; so the whole of the electric lighting by supply companies corresponds at present to only 6·64 per cent. of the output of this one gas company."

For perfect lucidity, we readily admit that the qualification "half-year's" should, in the latter portion of the sentence, have preceded the word "output"; but the context exonerates us from the absurd imputation of an intention

Digitized by Google

to mislead, and common arithmetic shows that there is no "ridiculous blunder." The reason why the half-yearly output was chosen at all was simply that we only happened to have those figures by us at the time, and did not care to make any assumption as to the remaining six months of the year.

We are further reproached with "coolly assuming" that an 8-c.p. glow-lamp is equivalent to "a gas burner consuming 5 cubic feet of gas per hour, which, by Act of Parliament, must give a light of 16 candles." To this we can only reply that it is as impossible to make an ordinary 5ft. burner give 16 candles as it is to make a man sober by Act of Parliament.

In order to get 16 candles out of 5 cubic feet of gas it is necessary to use a burner specially made for this purpose, and costing ten shillings. In speaking of the quality of gas, the use of this burner is always recognised, and London gas is kept as nearly as possible to this standard. But when we speak of the light yielded by gas burners that is quite another matter. It ought to be better known that new Sugg and Bray burners of the ordinary make hardly give two candles per cubic foot, and often less than $1\frac{1}{2}$; and we undertake to say that the average of ordinary burners in any average house in London, including flaring and dirt, is not greater than $1\frac{1}{2}$ candles per cubic foot.

Our contemporary says that "it has, moreover, been admitted by electricians over and over again, that for ordinary all-round lighting a so-called 16-candle incandescent lamp is not so effective as a 5-cubic feet gas burner." We have nothing whatever to do with the admissions of electricians. The 5-foot 16-candle convention is in our opinion more deceptive than the 2,000 candle-power arc lamp anomaly, and is less excusable by reason of the greater ease of the photometry. We speak with greater confidence since there is only one make of glow lamp in use in this country, and in electric lighting there is no special contrivance such as the "London Argand," costing from eight to thirty times the price, and giving twice as much light as the ordinary make.

No one but a crammer will disagree with "W. M. M." that the blind use of imperfectly understood symbols is fatal to progress, but that points to the need of a clearer comprehension of these symbols. Mr. Williams has set himself the task of attempting to rationalise the dimensional formulæ which have for so long been obscured by conventions and arbitrary assumptions; and "W. M. M." explains that he does not wish to suppress the whole theory of dimensions of fundamental units, but to use these dimensions merely for the purpose of obtaining numerical relations between quantities. If this can be done by a process of reasoning which can be clearly expressed, there is little to object to in our correspondent's argument. If it cannot, the statements quoted by "W. M. M." are opposed to such a limited meaning being given to units. We do not think a merely numerical interpretation is sufficient, for we have not yet seen in any text-book a satisfactory description of the method of obtaining the number which represents in electrostatic units a given quantity expressed in the electromagnetic system.

The statement that a cubic foot of water weighs about 1,000 ounces may be regarded as an illustration of a relation between units; for it is equivalent to saying that the amount of water contained in a cubic foot is about 1,000 times as great as the amount of water which weighs one ounce. In order to express a quantity of water in terms of one of these units, when it has been given in terms of the other, we have to use the numerical relation, 1,000. But this number does not express the ratio of a cubic foot to a pound, because in the first place such a relation is unintelligible until a specific substance is mentioned, and in the second place because it is only true for water. A relation between units is meaningless, unless the unit is understood to refer to something more than the mere measuring vessel, or other standard determining the magnitude of the unit; and it appears to us that to look upon dimensions merely from a numerical point of view will only increase the obscurity of the subject.

English "as she is writ" in the instructions to engineers for the use of Faber's slide rule is a fearful product. "Let it be supposed," says the book of instructions, "that a mountain river carries per second a volume of 1·64 cubic m., and that it possesses at a given place an available fall of 38·2 m.; what is the *force* obtainable at this place, *expressed in horse power*?" Nor is the situation improved by the information that "the unit of labour is the labour performed in a distance of 1 m. by a *force of* 1 *kilogramme per second*." We commend this derangement of epitaphs to our valued correspondent "W. M. M." and to his friends who think the study of the dimensions of units of no use. "A support lathe whose leading spindle has a rise of $\frac{1}{2}$in." appears to be pidgeon English for a screw-cutting lathe having a principal screw of $\frac{1}{2}$in. pitch. Considering, however, the fame of the eminent Bavarian house from which the instructions issue, we imagine that these instructions are really not primarily intended for engineers, but rather for persons who need a slide rule to perform such complicated arithmetical exercises as the following: "the price of one gross of *leadpencils* (144 pieces) is Mark 10,80; what is the cost of one?" But we fear that not even a study of dimensions will enable any calculator—with or without a slide rule—to deduce the cost from the selling price.

A gentleman named Smith has been rash enough to try to turn the phonograph to some useful purpose. Perhaps he was not aware that fate has decreed that this toy shall not be sold in this country. For his sins he soon found himself in the Law Courts; but, rash man that he was, he pushed on after obvious defeat to further discomfiture in the Court of Appeal. Why will men fight with the gods, and Mr. Smith with Destiny?

Digitized by Google

The Liverpool Overhead Railway.—Trains will be run on this line in October next.

Bray.—The electric lighting of Bray has become a *fait accompli*, and the system will be turned over to the Township Commissioners in the course of a few days.

Dover.—At a recent special meeting of the Town Council, the proposals of the Brush Company with regard to the lighting of the town were agreed to.

Chicago Exhibition.—All the Exhibition buildings, except two, are practically finished. The Westinghouse generators are to be 10,000 lighters, with one 20,000 light machine.

The City of London Electric Lighting Company.—The Board of this Company announce that the supply of current will be available, both day and night, on and after August 1.

The London-Paris Telephone.—A call office has been opened in connection with the London-Paris telephone at the West Strand Telegraph Office, Charing-cross. The office will be open day and night.

Electric Traction in Belgium.—The first electric tramway in Belgium, namely, that at Liège, is now being constructed by Van den Kerchove, of Ghent. Five cars, with 20-H.P. single-reduction 500-volt motors, are to be run.

The London Electric Supply Corporation.—The standard charge for current by this Company has been reduced to 7d. per Board of Trade unit. This change will take effect as from the commencement of the current quarter.

Winter Sessions.—Electrical Engineering courses will be begun early in October at University College, Bristol, and at the University College of North Wales (Bangor). For further particulars see our advertisement columns.

The Gresham University.—The Royal Commission inquiring into the granting of a Charter to the Gresham University is now sitting. The Bishop of London and the Rev. H. Wace, D.D., representing King's College, London, have given evidence in favour of granting the charter.

Bournemouth.—There was recently a slight explosion in one of the junction boxes of the Bournemouth and District Electric Supply Company. The damage done was unimportant, two of the fuses having merely shifted from their original position. The fuses were not melted.

Royal Institution.—At the general monthly meeting of this Institution, held on Monday, July 4th, the special thanks of the members were returned for the following donations:—Prof. Dewar (grant from Royal Society), £300; Ludwig Mond, Esq., £120; Hugo Müller, Esq., £50, for carrying on investigations on liquid oxygen.

Atmospheric Electricity.—A curious effect of the abnormal weather, says the *Indian Engineer*, was observed the other day on the Bengal-Nagpur telegraph system. It was found that the natural current of electricity prevailing was much greater than the artificial; so much so, that measuring the one numerically by four the other was represented by nine.

The Great Northern and City Railway.—At a recent public meeting resolutions were passed in favour of obtaining memorials, and the co-operation of the Islington Vestry to the end of getting a station erected somewhere in the Upper-street. Petitions were at once signed. It was also decided to send with the Vestry a deputation to the Company.

The Royal Commission on Electrical Communication with Lighthouses and Lightships.—This Commission is now taking evidence. Sir George Nares, Sir Leopold M'Clintock, Mr. F. Bedwell, hydrographer to the Telegraph Construction and Maintenance Company, Mr. Scott, secretary of the Meteorological Council, and Captain Anson, of the Ramsgate Coastguard, have been examined. The Commission has considered in detail the cases of the various lightships and light-vessels around the coast of England, Wales, and Ireland.

The New House of Commons.—Amongst the members of the new House of Commons are several well known to our readers, including Sir John Pender, K.C.M.G., Mr. J. S. Balfour, Hon. W. St. J. F. Brodrick, Mr. E. Boulnois, Mr. W. H. Fisher, Mr. J. W. Phillips, Mr. Sheriff H. S. Foster, Mr. W. Cuthbert Quilter, Mr. E. H. Bayley, and Col. Loyd. Sir G. Elliot, Mr. Hugh Watt, and Mr. Storey-Maskelyne failed to retain their seats; and Mr. James Pender, Mr. Thomas Parker, and Mr. Robert Hammond were also unsuccessful candidates.

Blackpool.—At the last meeting of the Town Council it was decided to lay down an electric lighting plant capable of supplying current for 13,500 8-c.p. incandescent lamps and 165 arc lamps. The estimated capital expenditure is £26,000, and the alternating-current transformer system is to be adopted. The Board of Trade unit will be sold at 6d. It was also decided to appoint a resident electrical engineer, and the Town Clerk and Chairman of the Committee were directed to advertise for one, applicants to state amount of salary required.

Institute of Chemistry.—At the examination in Practical Chemistry for admission to the Institute, held from Monday, 11th, to Friday, 15th inst., 37 candidates presented themselves, of whom the following 19 were successful:—Messrs. E. C. Baly, F. J. Bloomer, A. C. Chapman, J. C. Chorley, F. Dent, F. E. Francis, A. F. Fryer, F. J. Hambly, E. E. Johnson, T. Kendrew, C. Leigh, H. H. Mann, C. H. New, T. H. Norris, W. Orr, N. S. Rudolf, W. D. Sawers, A. E. Wareing, and Miss E. J. Lloyd.

Aluminium.—Towards the end of last year two German chemists, Herren Lubbert and Roscher, announced that aluminium, being attacked by wine, brandy, coffee, tea, &c., was not available for domestic utensils. At the meeting of the Académie des Sciences on June27th last, however, M. Ballaud rehabilitates in some measure the character of the aspersed "national metal." According to this gentleman months of experiment have shown him that aluminium *is* a suitable metal for domestic utensils, air, water, wine, beer, cider, coffee, milk, oil, &c., &c., having less action upon it than upon ordinary metals.

The Electrical Production of Ozone.—One use of ozone, on which Herr Frölich lays special stress in a recent lecture, is the disinfection and sterilisation of water. From recent experiments in the Siemens and Halske laboratory at Berlin, it appears that good results have been attained in producing ozone on a commercial scale by means of the silent electric discharge. An apparatus now at work in the laboratory yields 2·4mg. of ozone per second. Experiments are being made in supplying compressed ozone for technical use; and this has been accomplished with a pressure of nine atmospheres.

The Polyphase Current in France.—According to the *Revue Internationale de l'Electricité*, MM. Guitton and Bertolus, owners of the Oerlikon patents for France, have concluded a 30 years' electric light and power contract with the municipality of Romans. They propose to use a 1,000ft. fall, 17 miles distant from the town, and to employ polyphase currents. The Edison Company of Saint-Etienne also intends to adopt the polyphase system in carrying out the large transmission and distribution of power scheme voted by the Municipality. Near Montpellier a 200-H.P. fall is to drive polyphase dynamos supplying current to a group of villages.

The Electrical Utilisation of Water Power.—The new dam across the Colorado River at Austin, Tex., says the *Engineering and Mining Journal*, will raise the river 60ft. above its low-water mark. Mr. J. T. Fanning, consulting engineer for the city of Austin, states that the river above the dam has a drainage area of 40,000 square miles, and that in times of flood from 200,000 to 250,000 cub. ft. of water per second will pass over the crest of the dam. The dam is being built by the city of Austin to develop power to operate its water and electric lighting plants, and for manufacturing purposes. The dam will be 70ft. high and 1,125ft. long, and will set back water for some 25 miles.

Damage by Lightning.—A violent thunderstorm occurred in the West of England on Saturday last during which houses were struck at Bath, Bristol, Nailsea and Keynsham; a large number of cattle also were killed. At Burnett a fatal accident happened. Two men were at work together in a field, when they were both struck by lightning, one being killed and the other sustaining a severe shock. Three horses which they were working were all hurled to the ground, but not seriously hurt. Last Wednesday week a telegraph post in the suburbs of Gentilly (France) was struck by lightning, and the current was conducted by the

Digitized by Google

wires to the local telegraph office, nearly a mile off, and entirely destroyed the telegraphic apparatus in the operating room.

Hove.—The General Purposes Committee reported at the last meeting of the Improvement Commissioners, that they had completed the details with reference to carrying out a scheme for the transfer to a Company of the undertaking created by the Hove Electric Lighting Order, 1890, and presented the deeds. Mr. Woodman briefly reviewed the proceedings of the Electric Lighting Committee, pointing out that the Commissioners had been very carefully safeguarded by their solicitor. A certain portion of the town would have to be lit within sixty days of the signing of the documents, while the whole area would have to be lit with electricity ninety days later. The resolution was carried.

Melbourne.—During a severe storm which occurred in Melbourne some few weeks ago, an insulated overhead wire belonging to the New Australian Electric Light Company came down. Two passers-by set to work to coil the wire up, with the result that one of them was killed and the other severely injured by the 2,000-volt current. Two other persons also received shocks. The wire was finally severed by an axe and the current cut off. At the inquest the coroner said that he did not think that anything had transpired in the evidence to show carelessness or negligence on the part of the company. The jury found that the deceased was accidentally killed by coming in contact with a wire carrying an electric current, in an effort to save another man who was in contact with the same wire. They also found that there was no blame attached to any person in connection with the lighting.

Personal.—Mr. W. B. Esson, who has been for many years with Messrs. Paterson and Cooper, has recently transferred his services to the Gülcher (New) Electric Light and Power Company (Limited), Wellington-road, Battersea, S.W. Mr. Esson's private address is now Thrale Hall, Streatham, S.W. ——Mr. Spagnoletti, the well-known telegraph engineer to the Great Western Railway, will retire from the service of the Company in August on a superannuation allowance. We understand that next month Mr. Spagnoletti will take up the post of Managing Director to the Phonopore Syndicate.——Mr. Christian Gray, of the Silvertown Works, was attacked last Saturday by a lunatic workman, who subsequently committed suicide. Mr. Gray's injuries were, fortunately, not serious.——Dr. Werner Siemens, who was reported early in the week to be lying seriously ill at Hamburg, is, we are glad to learn, now much better. Dr. Siemens is in his seventy-sixth year.

Electric Lighting Notices.—The Hammersmith Vestry has received notices of intention to apply for Provisional Orders from the County of London Electric Lighting Company, and from the Putney and Hammersmith Electric Lighting Company. The Vestry have, however, decided that the necessary steps shall be taken for obtaining a Provisional Order for the electric lighting of the parish; and a special meeting of the Vestry will be held shortly, when a report will be submitted as to the probable cost and most convenient areas to be lighted. Similar notices have been received by the Holborn Board of Works from the County of London (North) Electric Lighting Company, and the Islington and General Electric Supply Company. The Poplar District Board have also received a notice from the County of London Electric Lighting Company. It was resolved that the Works Committee should consider the desirability of the Board itself applying for a Provisional Order.

Continental Strolling Players and the Electric Light.—The use of the electric light, writes an occasional correspondent, is spreading to the most out-of-the-way parts of rural France. Strolling players who travel about giving representations at the various rustic fairs generally include amongst their heterogeneous paraphernalia a small electric lighting plant, the dynamo being usually driven by the traction engine used for hauling the theatrical apparatus from town to town. Arc, not glow lamps, are preferred, and globes are conspicuous by their absence; so that the arcs serve the double purpose of giving light and of death-traps to the myriads of winged insects that are attracted by the beams. Spark protectors would, however, be a boon, as there are at times plentiful showers of hot carbon cinders, which alighting on the spectators beneath give rise to lively complaints. It is interesting to notice this enterprising use of the electric light, and credit is due to the rural blacksmiths who usually manage the plant. The lamps are generally remarkably steady and the brushes properly set.

The Late Mr. Cyrus Field.—The following letter appeared in *The Times* of Monday, over the initials W. H. R.:—

"Sir: Only those who were on board the 'Great Eastern' on August 2, 1865, can have any idea of the 'shock' which the sudden breaking of the Atlantic cable that day gave to those who were interested in the great undertaking that so far had progressed without impediment. Captain (now Sir) James Anderson, Mr. Thomson (now Lord Kelvin), Mr. Varley and the staff of electricians, the Directors, and their friends, all on board the great ship, in fact, were so elated by success and so confident of the accomplishment of the work that the sudden cessation of the strain on the indicator, and the cry that followed, 'The cable is gone!' produced an effect not short of consternation on everyone save one man—Cyrus Field. He rushed up on deck when the fatal announcement reached his ears in the saloon, made his way through the silent despairing group astern who were gazing into the sea in which thousands of fathoms deep their hopes were buried, satisfied himself that the cable was broken beyond remedy, and then, calmly surveying his associates without a trace of agitation on his face, said, 'Well, it's so. I must go down and prepare a new prospectus immediately. This thing is to be done,' and stalked quietly back to his cabin, where he set to work to write out the proposals for a new cable ere the end of the other had well settled down in the Atlantic. You have only done simple justice to the energy and commercial courage of Cyrus Field in your leading article of July 14th. I relate what I saw and heard on the occasion to which you referred."

The Telegraph and the Herring Fishery.—As an instance of the importance of the electric telegraph to our fishing population, the Fishery Board for Scotland, in their annual report, tell us that one Saturday morning a large shoal of herrings was discovered about three to seven miles off the Island of Stronsay by a few boats which happened to be at sea. Having ascertained the position of this shoal the officer wired the particulars, for the fishermen's information, to all the stations in Orkney, and on the Monday following every boat employed in the herring fishery in Orkney was on the fishing ground indicated. The result was that the heaviest fishing ever obtained in one day in Orkney, for the number of boats employed, was landed on the Tuesday. The number of boats fishing was 108, and their total catch was 5,400 crans, valued at £3,240. Consequent upon such a heavy and unexpected fishing, additional coopers, gutters, packers, barrels, and salt had to be immediately sent for from Wick so that the herrings might be cured while they were in a fresh state, and this again was accomplished by means of the telegraph. The officer of Shetland district reports that the telegraphic extensions there are being largely used for fishery purposes, and states that without the wires it would be almost impossible to carry on the herring fishery at those remote stations.

Toynbee Hall Electrical and Chemical Societies.—Last week a *conversazione* was held by the members and friends of these newly-formed societies. After an interesting lecture on "Pigments, Past and Present," Mr. A. P. Laurie, M.A., B.Sc., stated more particularly the object of the societies. The laboratories which were attached were intended only to supplement those already in existence in other parts of London by giving facilities for special work in which members might be engaged during the day. The work of the students would not be cramped by any hard-and-fast rules, and able men would superintend and advise them in their work. He believed there was a great future before them if they only moved in this direction. A small amount of apparatus had already been obtained, and the laboratories would be opened in the autumn. He appealed on behalf of the Committee to the heads of large manufacturing firms in London to give their help, as their small funds would be inadequate to carry on the work efficiently on the basis they had planned. Their initial expenses were already great, and aid from the affluent was sorely needed. Dr. Fison will have charge of the Electrical Department next winter, and will give a course of about 30 lectures dealing more especially with the mathematical calculations connected with the science. Mr. Laurie, we believe, will take charge of the Chemical Department. All communications to be sent to Mr. Jameson, Toynbee Hall, 28, Commercial-street, Whitechapel. The President of these Societies is Mr. Preece, and among the Vice-Presidents are Prof. H. E. Armstrong, Prof. W. C. Roberts-Austen, Prof. Silvanus Thompson, and Mr. G. H. Robertson.

FEED-WATER HEATERS AND ECONOMISERS.*

Generally speaking, feed-water heaters are vessels for heating the feed by exhaust steam, and economisers utilise the heat of the flue gases for that purpose; by means of the latter the feed-water can be raised to much higher temperatures than with the former.

Feed-Water Heaters.

The maximum temperature to which the feed can be heated by the exhaust steam is always below that at which the exhaust enters the heater. The table below shows the percentage of saving effected for different temperatures of the feed up to 212° F.

Temperature of Feed Water. Degrees.	Heat Units per lb. water evaporated	Percentage increase of heat per lb. of water.
212	212	
200	978	1·2
175	1,003	3·8
150	1,028	6·4
125	1,053	9·0
100	1,078	11·6
75	1,103	14·2
50	1,128	16·8
32	1,146	18·6

From the average results of different experimenters, it has been found that in the heat transmitted per square foot of surface per deg. Fahr. the difference of temperature per hour is as follows:—

	British thermal units per hour. Heating water.	Evaporating water.
Surface of copper pipes	310	1,000
Surface of copper plates	275	530
Surface of cast-iron plates	80	180

These results were obtained when the surfaces of plates were in good condition. The increased rapidity of transmission when evaporating as compared with heating is due to the quicker circulation of the water as it reaches boiling point.

If W = Weight of water in lbs. per hour.
M = Time occupied in heating the water (*i.e.*, the time in which each particle of water passes through the heater) in minutes.
R = Rate of transmission per hour in British thermal units for 1°F. difference of temperature (see above table).
H = Area of heating surface in square feet.
T = Temperature of exhaust steam (Fahr.).
t = Temperature of feed, hot.
t_1 = Temperature of feed, cold.
U = British thermal units used in raising temperature of feed-water, per hour.

Then
$$U = W(t - t_1)$$
$$H = \frac{60\,U}{R\,M\left(T - \frac{t+t_1}{2}\right)}$$
$$M = \frac{60\,U}{R\,H\left(T - \frac{t+t_1}{2}\right)}$$

and if R = 200, T = 228deg., t = 190deg., t = 40deg., M = 10deg.; $H = \frac{W}{25}$, *i.e.*, 1 square foot of surface to every 25lb. of water.

In many heaters as much as 1 square foot to every 15lb. is given. The heat surface should be from 1 to 2 square feet per actual horse-power of boiler (actual horse-power = 30lb. water evaporated per hour).

It is better that the feed-water should be on the outside of the tubes of the heater, so that the sediment or scale may not choke the tubes. If the capacity of the heater be large, so that the water passes through slowly, time is allowed for impurities to be deposited at the bottom of the heater. In fact, for many kinds of feed-waters the heater is an excellent purifier.

* All rights reserved. From a forthcoming work by Messrs. Geipel and Kilgour. (*The Electrician* Printing and Publishing Company.)

Economisers.

Fuel economisers will heat the feed up to the temperature of evaporation, and therefore give better results than feed heaters. They are, however, not of use unless the temperature of the gases leaving the boiler exceed that required to cause a good draught in the chimney, say 350° F. Owing to the deposit of soot on the heating surface at the end of the boiler flues, it is, perhaps, advisable to have the boiler proportioned to its work, so that the gases leave at a temperature of between 500deg. and 600deg., and to use the balance of the heat available, viz., 500deg. or 600deg. – 350deg. in an economiser such as Green's, where the heating surface is kept clean, and therefore efficient, by means of mechanical scrapers. Again, the difference of temperature between the water in the economiser and flue-gases is greater than that between the flue-gases at the end of the boiler and the water in the boiler, which partly accounts for the greater efficiency of the heating surface of the economiser. There is the additional advantage that the wear and tear of the boiler is greatly reduced by the uniform temperature resulting from the hot feed, and by the deposit of impurities and scale which remain in the economiser and are readily withdrawn from the bottom thereof.

To ascertain the saving by the use of an economiser—

If u_1 = Heat in British thermal units required to raise 1lb. of steam from temperature of cold feed,
u_2 = Heat units used in raising temperature of 1lb. of feed-water from t_2 to t_1.
t = Temperature of steam Fahr.,
t_1 = Temperature of feed (hot), Fahr.,
t_2 = Temperature of feed (cold), Fahr.,
W = Water to be heated in lbs. per hour;
u_1 = $1{,}082 + {\cdot}305\,t - (t_2 - 32)$,
u_2 = $t_1 - t_2$.

Saving per cent. =
$$100\,\frac{u_2}{u_1} = \frac{(t_1 - t_2) \times 100}{1{,}082 + {\cdot}205\,t - (t_2 - 32)}.$$

Total saving per hour = $u_2 \times W$.

Saving per Cent. effected by Economisers when the Feed-Water is Heated to the Temperature of Evaporation.

Temp. F°. of cold feed.	Steam pressure in lbs. above atmosphere. 80	100	150	200
32	24·7	25·8	28	29·6
50	23·2	24·3	26·4	28·2
100	19	20·1	22·2	24

Messrs. Green find that under ordinary working conditions with the hot gases entering the economisers at about 550°F. and leaving at 325°F., each square foot of pipe surface heats 7lb. of water about 150°F. above the temperature at which the water enters the economiser, or transmits rather over 1,000 B.T. units per square foot per hour; or about 4 B.T. units per square foot of surface per 1°F. difference of temperature between inside and outside of tube, which is a very slow rate. If the pipes could be kept absolutely clean, a considerably higher duty might be obtained. At these low temperatures soot forms very rapidly on the surface, and it is due to the efficiency of the means of keeping a clean surface that the best results are obtained. After much experience Messrs. Green have adopted a special form of mechanical scraper, balanced so as to reduce the power required for driving. For a 2,000-sq. ft. economiser a 4-in. engine at 60 revolutions is required, and other sizes in proportion. The mean speed of the scrapers is one yard per minute. They have tried removing soot by means of flame, but this caused unequal expansion and contraction, and so impaired the life of the economiser; also by means of steam, which made a settlement of mud round the bottom of the tubes, tending to corrode them rapidly. Various materials have been employed for making the tubes, including wrought iron, cast iron, steel, brass, and copper, all of which are more or less quickly attacked by the sulphurous fumes in the flue gases; they now find a special mixture of cast iron gives best results; that which they use at present

Digitized by Google

has a tenacity 75 per cent. greater than the metal originally used. The tubes are 4in. diameter inside and $\frac{3}{8}$in. thick; each tube is tested to 600lb. per square inch or more, and may be relied on to stand a 200lb. working pressure. The tubes, which are 10ft. long, are set in rows generally four to ten pipes wide, and 8in. from centre to centre of pipe. The width of the economiser between the brick sides = 8in. × number of rows of tubes + 16in. or more, which allows of a space at least 9in. wide along one side for man room. There should be about 3ft. clear space outside of one of the side walls for room in cleaning.

If the feed water is quite cold, say 60°F. or under, there is a liability of sweating on the outside of the tubes by condensation of any vapour in the flue gases. This sets up a rapid corrosion of the tubes, to overcome which it is advisable to connect the hot-water outlet and the suction of the feed-pump by a small pipe, say $\frac{3}{4}$in. in diameter, to slightly raise the temperature of the cold water before entering the economiser.

In ordinary practice the heating surface of the economiser is about 60 per cent. of that of the boilers, and as each tube has 10ft. of surface, number of tubes = boiler heating surface $\times \frac{6}{100}$.

Another rule gives—

1 tube for 3 I.H.P.
„ 70lb. water per hour heated.
„ $2\frac{1}{3}$ actual boiler H.P.

The weight of Green's economiser averages about eight tubes per ton, so that 80 tubes = 10 tons.

Messrs. Babcock and Wilcox make an economiser of wrought-iron tubes lying in an inclined position with a mud drum at the bottom, very much upon the principle of their tubular boiler without the steam drum. The tubes are kept clean by means of steam jets. As the soot falls clear of the tubes, the objection mentioned above does not apply apparently to this type of economiser.

GUTTA-PERCHA.

TLe following is translated from *L'Industrie Electrique*, and is a report of a Paper read before the Société d'Encouragement in June last by M. Jungfleisch. An abstract of a Paper read before the same Society by M. Sérullas appeared in *The Electrician* of May 20th; and in the following issue an article appeared traversing several of M. Sérullas' statements :—

Two months ago M. Sérullas, in giving an account of his expedition to Malaysia to discover the best gutta-percha tree, alluded to a new method of obtaining gutta-percha, but did not enter into details.

Having, in conjunction with M. Damoiseau, investigated the principal constituents of gutta-percha, the author succeeded in obtaining all three of them in a crystallised state, and in ascertaining some precise data with respect to their nature. The variability of commercial samples and the consequent impossibility of reproducing with any degree of certainty the results obtained with any given sample, however, made him postpone publication. The wish to carry on these investigations with gutta-percha, the origin of which was certain, called the author's attention to the results of the French expeditions then at work elucidating the question of our gutta-percha resources, and especially to the results obtained by MM. Seligmann-Lui and Sérullas.

In fact, until quite lately, only vague information had been available with respect to gutta trees. The plants themselves had, indeed, been described with all possible botanic science, but no relation had been established between a given plant and the quality of its gum. The French expeditions fixed attention on these important points. In 1888 M. Sérullas had already sufficiently numerous data to make sure that Hooker's *Isonandra gutta* was the gutta plant *par excellence*.

By all accounts, emanating from this source and from foreign expeditions, the Malay method of working, an essentially destructive one to the *Isonandra* forests, was *the* cause of the approaching exhaustion of these forests, and, therefore, of the exhaustion of a raw product now become indispensable to the electrical industry. The Malays, with their present mode of operation, could only work trees 28 to 30 years old, or shoots of from 14 to 15 years; and the tapping of a tree of 30 only yielded at the most 265 grammes (9½oz.) of raw gutta, which was often mixed with half its weight of foreign matters of no commercial value. Setting to work with more care than the Malays, M. Sérullas had only been able to extract 220 grammes from a 30-year old tree; the gum was, however, purer than that obtained by the natives. M. Sérullas saw a tree 1·2 metres in diameter worked, and it only gave 382 grammes of raw gum.

Such improvident and unproductive processes were very amazing when the enormous consumption was called to mind. M. Trevenen, taking note of the gutta, good or bad, exported from the Malay ports in 1884, arrived at a total of 3,144,847 kilogrammes (3,200 tons), an amount which, according to the data mentioned above, corresponded to the destruction of more than 12 million 30-year old *Isonandra*. However, *Isonandra gutta* were not the only trees cut down, and it might be remarked that similar species gave bad gutta in abundance. But it was nevertheless certain that production tended to rapidly diminish as consumption increased. In 1881 the International Congress of Electricians which met in Paris gave utterance to the fears which this state of things gave rise with regard to the future of the electrical industry. Recently, and on all sides, the big European powers had been moved to safeguard such an important interest by acclimatising the *Isonandra* in their colonies, and by pushing its cultivation. The remote results to be expected from plantations of this kind undertaken 20,000 kilometres from Europe, and on a scale necessarily gigantic if they were to be of any good, would explain the feeble efforts hitherto made. The difficulties encountered by those who endeavoured to bring the European powers to a proper appreciation of the matter made the author doubt the efficacy of the schemes proposed, and led him to try and see if the question could not be attacked in another way.

An examination of the samples brought home by M. Sérullas in 1888 showed that gutta was present in all parts of the plant; the parts other than the trunk contained gutta in amounts apparently very much greater than the trunk itself yielded to the Malays. Was it not possible that the coagulable matter of the latex might accumulate in some part of the plant whence it could be obtained by means more delicate than those employed by the Malays? If by any chance these parts were such that we might separate them from the plant without injuring it, the problem would have made a long step towards solution. Previous unpublished investigations, indeed, left no doubt as to the possibility of finding solvents enabling us to extract gutta from these parts, and to extract it alone. M. Sérullas, who was then setting out again for Indo-China, was good enough to undertake the verification of the numerous hypotheses which a series of trials carried out with this leading idea involved; he also arranged to send home samples gathered under agreed-upon conditions so as to permit of the necessary experiments. Leaving aside mere attempts and suppositions shown to be inaccurate, it only remained, said the author, to point out the facts which these experiments had established.

The solvents which enabled us to extract gutta-percha from vegetable cells were many, but toluene seemed the best in the present case; it dissolved the three principal constituents of gutta-percha, and it did not dissolve in appreciable quantity the substances which accompanied it, with the exception of a little chlorophyll. Comparative tests were made with—(i.) Leaves dried in air, and sent dry; that was to say, exposed to the oxidation of the air. (ii.) Fresh leaves despatched in water, rendered antiseptic, and dried on arrival. (iii.) Dried shoots deprived of their leaves. (iv.) Two-year-old wood, dried and deprived of leaves.

Contrary to anticipation, all these portions supplied much the same amounts of gutta, amounts which were always large. This first result enabled one to predict a favourable issue. It immediately fixed the attention on the part of the plant the most advantageous for treatment. By plucking the leaves, which the plant constantly renewed of itself, the effect upon the development of the plant was reduced to a minimum. The method of extraction was, moreover, a very simple one. The pulverised material was first exhausted by digestion at 100°C., and then by being placed in a solvent, such as toluene. A solution of gutta having a green tint, owing to the presence of a little chlorophyll, was obtained. The direct evaporation of the solvent not being possible without injury to the product, the toluene was carried off by a gentle stream of vapour of water—that was to say, at a maximum temperature of 100°C. For every volume of water evaporated four volumes of toluene were carried off, the gutta remaining. The toluene was completely expelled by prolonging the action of the vapour on the mixture, which was kept at a temperature of 100°C., and in a state of agitation. The yields obtained from the various parts of the plant mentioned above fluctuated between 9 and 10·5 per cent.; they were, therefore, much better than could have been expected.

But it might be asked whether these large yields were not due to the mixture with the gutta of some of the vegetable substances dissolved by the solvent! At first glance the appearance of the resultant product seemed to support this hypothesis; the substance being greenish, whilst the Malay gutta was red. In reality,

Digitized by Google

gutta-percha, naturally almost colourless, was tinted in the former instance by traces of chlorophyll, which could be eliminated by appropriate treatment, and in the second instance by fragments of bark and special vegetable substances, from which the material obtained by the use of solvents was entirely free. The point of capital importance was that all competent persons, whether merchants or manufacturers, who had examined the gutta produced by the new process, had unanimously considered it to be very superior and comparable with the best descriptions which were no longer procurable, much to the regret of the electrical industry. Larger quantities must evidently be made to enable investigations to be made under conditions likely to fix attention on certain details. It was, however, even now possible to assert that solvents would lend themselves if judiciously used, not only to the extraction of gutta-percha but to its commercial treatment and purification.

The author then exhibited a number of samples of gutta-percha obtained by the solvent process.

Contrary to what might have been anticipated from the great oxidability of gutta carbon compounds, the leaves which were sent home much exposed to the action of constantly renewed air yielded a product the quality of which was excellent. It was permissible, therefore, to anticipate an exploitation of the surviving *Isonandra* of Malay, which should be based on the plucking of the leaves and their exportation in a dry state to Europe, where they would be submitted to the solvent process. The very marked characteristics of these leaves would protect manufacturers from fraud, and would give them with some certainty a gutta of excellent quality. Moreover, if it were a question of producing leaves or small branches the immediate return would encourage planters in the extreme East to an outlay the reward for which could not be delayed. Under these circumstances it was permissible to expect more from private enterprise than from the undoubtedly great perseverance and prescience demanded of European States.

Meanwhile it was allowable to anticipate the stoppage, more or less rapid, of the present mode of working. The Malays would sell leaves, which were easy to gather, quite as readily as the gutta itself, which was difficult to extract. Thus, a 30-year old tree, according to M. Sérullas, bore from 25 to 30 kilogrammes of green leaves or about 11 kilogrammes of dry leaves, which would yield by the new process from 1,000 to 1,100 grammes of gutta, while if the tree itself were cut down it would yield at the most 265 grammes. Moreover, according to Malay methods, many times the amount of gutta obtained from the trunk was left in the leaves and small branches. The natives would, doubtless, soon understand that leaf picking carried on during several seasons of the year must bring them in much more money than the laborious work of felling the large trees. Carrying on the same train of thought, a 30-year old tree need only give 7 kilogrammes of fresh leaves, which was but a small yield, to give a continuous return equal to which it would give but once if cut down. Trees of every age and size, at present without immediate use, would, moreover, be available for paying working.

The complete transformation of the present mode of obtaining gutta-percha seemed capable, therefore, of assuring a proper supply of this interesting substance to the European market. It was also to be hoped that private enterprise, by undertaking plantations, to which it seemed possible to promise quick returns, would see to the future.

ELECTRIC RAILWAY MOTOR TESTS.*

BY PROF. GEO. D. SHEPARDSON AND EDWARD P. BURCH.

The experiments here discussed were undertaken for the purpose of obtaining definite information about the performance of electric railway motors under various conditions. There is a diversity of opinion about the relative merits of regulation by rheostat and by commutated fields, the use of one or two motors on a car, value of wetting rails, causes of "bucking," and other points. It is commonly understood that electric roads using rheostat regulation require larger capacity at the generating station than those using the commutated fields. It is also known that one large road has substituted rheostat regulation for commutated fields on all its motors. The tests were conducted for the most part by Mr. Edward P. Burch, a senior in electrical engineering in the University of Minnesota, and by courtesy of the Minneapolis Street Railway Company. Most of the tests were made upon a No. 6 Sprague double reduction motor. Some experiments were also made upon a single reduction motor. Each car axle is replaced by a short shaft carrying a heavy cast-iron wheel with solid web, upon which two oaken blocks are bolted for use as a brake. This was made into a Prony brake. The speed was measured by a common speed indicator with soft rubber tip to prevent slipping. For slow speeds a stop-watch was used, the time for five revolutions of the car wheel being noted. Current and potential were measured by new Weston instruments, about 12ft. distant from the motor.

The Sprague motor armature has 56 sections of eight turns each of No. 12 B. and S. gauge wires. The speed reduction ratio is 11·765. The field coil as used at first was in three sections, coil A 700 turns, coil B of 820 turns, and coil C of 620 turns, all being No. 12 B. and S. gauge wire. By means of the well-known barrel switch these coils are thrown into the following combinations:—

Clip 2, Coils A, B and C in series.
Clip 3, Coils A and B in series.
Clip 4, Coils A and B in parallel, C in series.
Clip 5, Coils A and B in parallel.
Clip 7, Coils A, B and C in parallel.

Several sets of efficiency tests were made with each combination. The three pairs of coils were then replaced by a single pair of coils connected in series, and having several terminals so that the number of turns used might be altered. This was used in connection

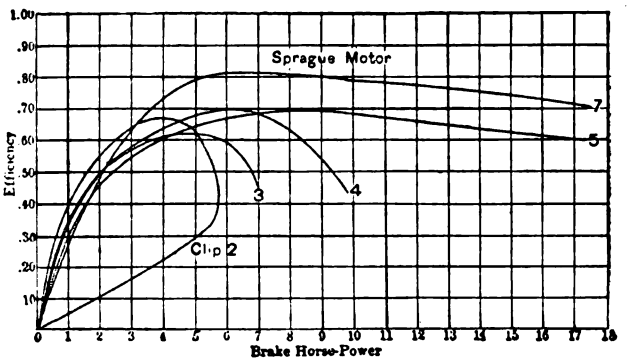

FIG. 1.

with a Thomson-Houston rheostat. In comparing these curves among themselves and with the result of other experiments, it should be noticed that the voltage was considerably below that for which the motors were designed, and that the power delivered was measured at the car axle. The Foucault currents in the cores were probably greater than in the new armatures. With the same armature and fields the efficiency is a few per cent. higher cold than when hot. It has been the aim to run as nearly as possible at the temperature of ordinary running, so that the fields were comfortably warm but not hot. It is confidently believed that the efficiency of these machines would be considerably above 90 per cent. if taken at armature shaft and with full voltage.

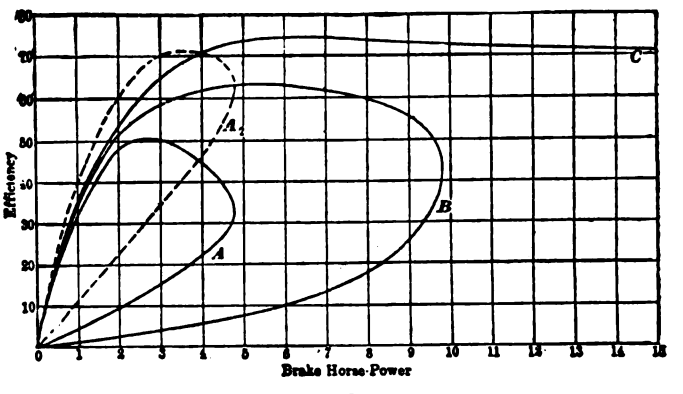

FIG. 2.

Fig. 1 shows efficiency curves for the motor, with different combinations of the field coils.

In Fig. 3, curves A and B show efficiency of the machine with 857 and 611 turns of No. 7 wire in the field coils. It will be noted in Figs. 1 and 3 that the motor has highest efficiency with the larger number of turns on field coils until the iron is saturated, when the better efficiency is given with smaller number of turns and consequent lower resistance in field. This shows the advantage of working on the fifth and seventh clips with barrel regulator, or of cutting out part of the turns on field when the load is heavy. On starting the car the current is very heavy and the field is saturated with a small number of turns; hence the torque with a given current is nearly the same, whatever the windings of the field. The speed and counter E.M.F. are small at starting; hence the potential difference at the armature brushes should be reduced until it passes only enough current to start the car without jerking. The easiest way of reducing the potential difference at the brushes is by interposing

* Abstract of a Paper read before the American Institute of Electrical Engineers.

Digitized by Google

resistance; and the heat developed by the C^2R can be cared for more easily and cheaply in an open rheostat than in the field coils. Rheostats of iron and mica are cheaper and more heat-proof than cotton-covered wires. This forces the conclusion that for the heavy load due to accelerating the car at starting, the field should have the smaller number of turns, and as the car reaches normal speed, and the horse-power and current become less, the efficiency of the motor would be raised by increasing the number of turns in the field. This conclusion is exactly the reverse of the common practice of manufacturers who sacrifice some efficiency for speed at small horse-powers. It is also in line with the experience of the road mentioned, that replaced the commutated fields with a single series coil of No. 7 wire, and later with No. 5 wire. This heat loss could be saved and the average efficiency raised by using the two motors in series

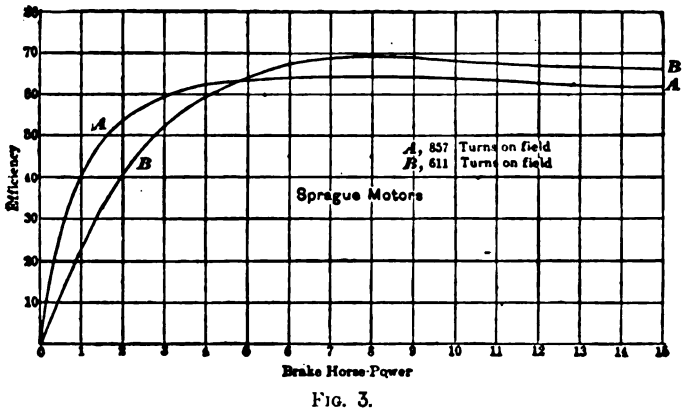

FIG. 3.

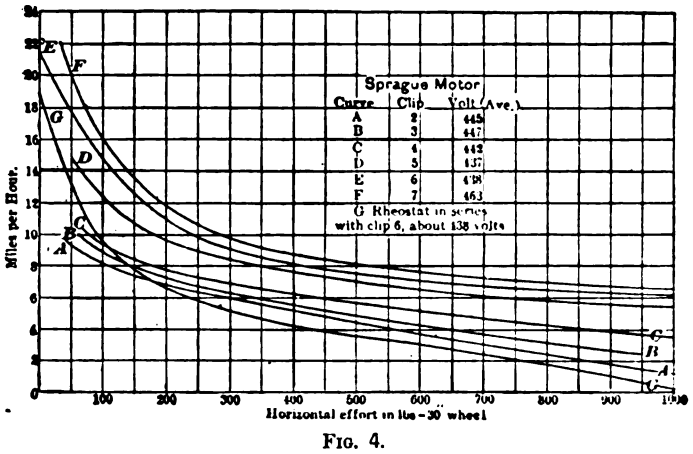
at the start, and afterwards cutting out one or putting the two motors in parallel if necessary, as the speed increases and horse-power decreases. An average of 12 tests on the road shows that with two motors on a car it requires 27 per cent. less current if only one is working.

In Fig. 2, curve A shows the efficiency of a Sprague motor with single pair of coils when the whole of a Thomson-Houston rheostat is in circuit. B shows about three-fifths of the rheostat in use; and in C it is all out. The dotted line A_2 gives the efficiency as calculated from the difference of potential about the motor alone. Curve A_2 is not strictly comparable with the others on account of the necessary variations in the voltage at the motor; but it does show the increased efficiency to be obtained by utilising the superfluous voltage in a second motor in series. In this connection it is interesting to note that the resistance of rheostat, as calculated



Miles per Hour.
Horizontal effort in lbs.-30" wheel

F 7 463
G Rheostat in series with clip 6, about 438 volts

FIG. 4.

from current and potential difference, decreases with increase of current. This is as expected, since the larger part of the resistance is due to surface contact between the plates of iron in the rheostat, these being pressed together more closely as the iron heats. A similar effect, but much more marked, has been noticed in earlier experiments by one of us with alternate plates of carbon and iron.

Figs. 4 and 5 show curves of torque, speed and horse-power referring to the No. 6 Sprague motor. In Fig. 5 A shows horse-power and horizontal effort on a 30in. wheel; B, C, D, E, and F clips 2, 3, 4, 5, and 7 respectively. Fig. 6 gives curves of current, torque, speed, and efficiency from a 15 H.P. Thomson-Houston single reduction motor. The reduction ratio is 4·78.

A number of load diagrams are given in the Paper. One of these, relating to the Minneapolis Street Railway Company, Station 1, shows a current varying from 1,300 to 2,700 amperes.

The "bucking" of street car motors is a subject of considerable interest to street railroad men, although it seems never to have been discussed in public. It sometimes happens that an electric car suddenly stops, as if by collision. In some cases the car refuses to go further, but usually it goes ahead immediately, as if nothing had happened. This is known among railroad men as "bucking." To explain the action, it is noted that in common practice the motor fields are connected between the armature and trolley, the armature being grounded at the negative brush. If a second ground occurs on any part of the machine except between

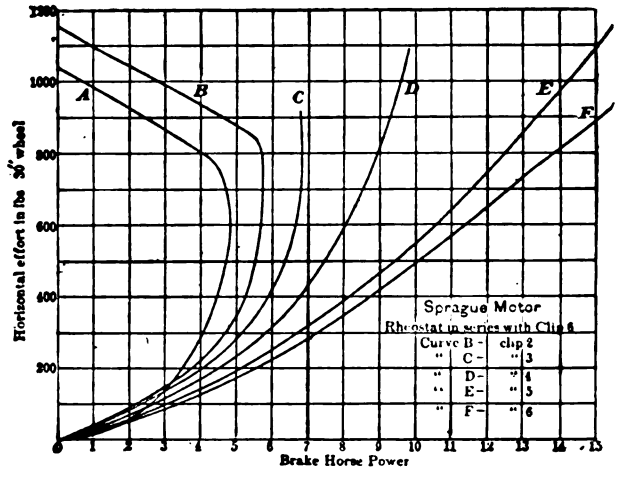

FIG. 5.

the fields and trolley, a heavy current passes to ground, giving an intensely strong field, while the armature is short-circuited by reason of the two ground connections. It therefore acts as a dynamo short-circuit, and becomes a powerful electric brake, that stops the car very suddenly.

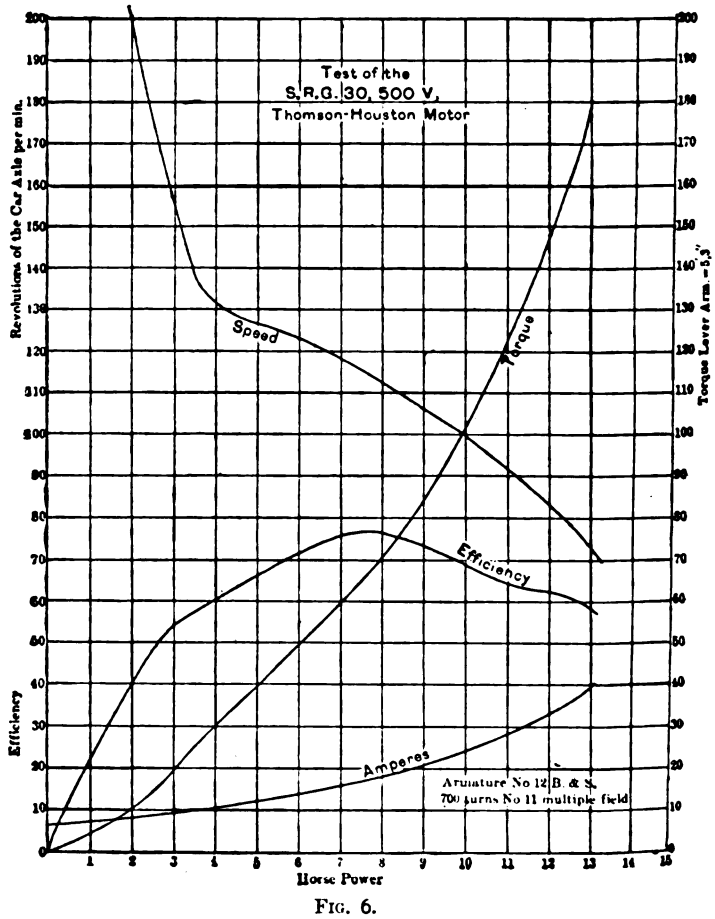

FIG. 6.

Sometimes a car will buck at regular intervals. Examination of the motor shows a small bright spot on one brush, which rolls to and fro at the contact between brush and commutator. This is intensely bright, like a ball of melted metal, and grows larger until nearly three-fourths of an inch in diameter, when it suddenly

Digitized by Google

explodes with considerable noise and a blinding flash, and at the same instant the motor bucks. The car goes on again at once, and the cycle is repeated again in the time required to run from one-half to four city blocks at ordinary speed. In such a case the bucking is stopped by shifting the brushes. The carbons are sometimes placed carelessly, so that the presser-foot rests partly on the carbon and partly on the holder. This presses the carbons against the commutator so as to give good contact until the carbon wears off a little, when the presser-foot no longer feeds in it. Vigorous flashing occurs, culminating in a buck, the shock of which may jar the presser-foot into its proper position, when the motor runs on as if nothing had happened, leaving behind no trace to indicate the cause of trouble.

The motors with Gramme ring armatures are known to buck more frequently than those with drum armatures. These buck worse when run on the "loop," *i.e.*, with part of the field coils cut out, some of them bucking regularly every time the loop is cut out This is one reason why the use of the loop has been abandoned on this road except in a few cases. In searching for a reasonable explanation for all these cases in which no second ground connection existed, it was noticed in each case that bucking was more liable to occur when the field was comparatively weak; also where the armature reaction was greater. In each case the neutral line is shifted, and the coils under the brushes are in an active field. The large current in short-circuited coils further distorts the field, and the sparking at the brush becomes excessive, causing a vigorous flashing. As soon as the counter E.M.F. in the sections leaving the brushes rises above 20 volts, the arc is carried around from one brush to the other, thus grounding the positive brush and short-circuiting the armature, which then acts as a dynamo and causes the motor to buck. Such bucking is usually less vigorous than when caused by a dead ground, on account of the resistance of the arc. This explanation covers all the cases noted.

Such being the causes of bucking the remedies are plain. Armature reaction must be reduced. An obvious remedy for bucking caused by direct grounding would be to connect the fields between armature and ground instead of between armature and trolley. With such an arrangement, a ground on the fields would simply cut out a part of the coils, and cause that machine to work harder. A ground at brush between armature and field would cause a sudden forward impulse on account of the field requiring some time to lose its magnetism, and would blow the fuse. A ground on armature would likewise cause a sudden forward impulse and blow the fuse. With such an arrangement there would be no true bucking except in case of the flashing as noted. An incidental advantage of this arrangement is that the difference of potential between the field and the frame of the machine is reduced to a few volts caused by the drop through the field; hence there is less danger of grounding the field. The increased difference of potential between armature and core is only a few volts, and would not affect the insulation very much.

VOLTAIC CELLS WITH FUSED ELECTROLYTES.*

BY J. BROWN.

In comparisons of the observed electromotive forces of voltaic combinations with their theoretical values, as given by Thomson's law, the discrepancies frequently observed are probably to a large extent caused by the action of the solvent—usually, of course, water—especially in the cases of easily oxidizable metals, such as magnesium and aluminium. The solvent may possibly act as an electrolyte, or it may act indirectly by the formation of insoluble protective films on the metals. There is also some uncertainty as to how far the heats of solution of the products formed in the cells are adjuvant. These difficulties led to the consideration of a simpler form of cell, in which the solvent is abolished and the liquidity of the electrolyte is produced by fusion.

I.—*Cells containing Single Chlorides.*

Certain chlorides were chosen for the electrolytes as being fusible and otherwise suitable. The cells were of the two-fluid type, Zinc | $ZnCl_2$ | $MgCl_2$ | Magnesium.

Although the action of atmospheric oxygen cannot be said to be excluded, and there was probably some action between the two chlorides themselves, the results correspond much better with theory than those obtained with the aqueous form of cell. In the actual experiments one of the chlorides was fused in a V tube, into one limb of which a short straight tube, plugged below with asbestos and containing the other chloride, was then inserted. Precautions were taken to mitigate any effects of the mixture of the two electrolytes and keep the temperature uniform in the cell. The appropriate metals were placed in their chlorides in the tubes, and the electromotive force of the cell so formed was carefully measured on a Thomson electrometer, and compared with that of a Daniell cell, whose force was estimated at 1·13 volts.

A set of experiments was made on all possible combinations of the metals silver, copper, tin, lead, cadmium, and zinc in their chlorides. The theoretical electromotive force was assumed to be proportional to the difference of the combining heats for chlorine of the two metals in any given cell. This difference divided by 50,130, the heat-equivalent of the Daniell, gives the theoretical force of the cell in terms of the Daniell; or the heat-equivalent of each metal was first divided by 50,130, and the difference of any two quotients so obtained taken as the theoretical electromotive force for the cell containing the corresponding metals. On comparing the values so found with the observed electromotive forces there was fairly good agreement in cells containing any combination of zinc, lead, and tin, but not so good where silver, copper, or cadmium was concerned. It was found, however, that the application of certain corrections to the quotients for each metal as described above gave theoretical values in much better agreement with the experimental results, so much so that out of the fifteen observed cases only two differ as much as 0·03 from theory. The results are given in two tables, one containing the uncorrected and the other the corrected results.

The physical cause underlying these constants is believed to be connected with the higher temperature of the experiments as compared with that at which Thomson's heats of combination (the data employed in the theoretical calculation) were obtained. This view was confirmed by experiments on cells consisting of a single chloride only fused in a V tube with a piece of the metal contained in it inserted in each limb and connected with a galvanometer.

On heating one limb more than the other a current was produced in all cases except that of cadmium, the hotter metal being the positive pole. Metal was transferred from the hotter to the cooler pole, showing the electrolytic nature of the phenomenon, and suggesting, in the light of Thomson's law, an increase with temperature of the combining heats of the metals with chlorine, conjoined with a possible Peltier effect.

The reversibility of some of the cells was tested by passing currents through them in opposite directions and noting the electromotive force after each current had passed for some minutes. In the combinations, zinc-copper and zinc-lead there was no evidence of polarisation; with zinc-tin a minute effect, and only in the case of zinc-silver was there distinct polarisation amounting to about 2·4 per cent. of the whole force of the cell.

II.—*Cells containing Double Chlorides.*

As stated above, it was desirable to test cells in which the easy oxidisable metals such as magnesium and aluminium took part. The difficulties of working with the chlorides of these metals in the fuse state were got over by employing their compounds with alkaline chlorides, and the same method was adopted with the infusible ferrous chloride. Although the alkaline chloride may here be said to become the solvent of the metallic chloride combined with it, it is assumed that owing to the high combining heat of the alkaline chloride, and the fact that its anion is the same as that of the chloride combined with it (or dissolved in it) no serious complication is introduced by its direct action on the metals, as in the case of water when used as a solvent. The heat of solution of the one chloride in the other must, however, be considered, and in order to avoid, as far as possible, complications from this source, it was found best that in any given cell the two chlorides employed should be either both double or both single. Experiments were made on cells containing all possible combinations of the metals, silver, copper, tin, lead, iron, cadmium, zinc, aluminium and magnesium, in their double alkaline chlorides. The experiments were carried out in the same way as that described for single chlorides, with the result that in the cases of aluminium and magnesium the difference between experiment and theory does not exceed 0·2, while in aqueous cells it is found to be from four to five times as great.

The use of a correction for each metal in the way described above produces a still better agreement. After the application of the nine corrections required, the difference in no case, out of the thirty-six pairs examined, exceeded 0·07, which may be considered satisfactory taking into account the complication introduced by the alkaline chloride. The results for this set are also given in tables.

Since writing the above Paper my attention has been called to a Paper by L. Poincaré (*Comptes Rendus*, Chap. X., page 339), in which there are described some experiments on the thermo-electromotive forces of zinc and tin in their chlorides at unequal temperatures. The force of a zinc | $ZnCl_2$ | $SnCl_2$ | tin cell is also measured, and gives a result very near nine. M. Poincaré considers that in calculating the theoretical values for such cells the heat of fusion of the salts should be considered. It would seem that there may be on theoretical grounds some doubt on this point. Data for deciding it experimentally are not available.

MOTORS AND THEIR MODIFICATIONS.

The recognition of one's environment and the adaptation thereto are among the first essentials of happiness. When the square man finds himself in a round hole, one or the other—he or his environment—must give way if existence is to be endurable. And as with men so with machines, progress consists in development rather than in creation, and by far the largest proportion of mechanical inventions are adaptations and not new species. Sometimes the evolution is so gradual that the history is hard to trace. No one can point to the first steam engine or to the first dynamo, but no sooner had these machines become practicable than they began to be adapted to one special use or another. A new need has generally called forth a new modification; but while electrical energy is so readily applicable to widely different purposes dynamos and motors have appeared in less numerous forms than steam engines. The factory engine, the marine engine, and the locomotive differ more, both in outward appearance, in the nature of their work, and in the details of their design, than any classes of dynamos. We have alternate-current and continuous-current machines, it is true, and the latter exhibit important differences between constant-pressure and constant-current machines; so different, in fact, that the one would be useless if put to do the work of the other. But great as these differences may be, no one but an expert could possibly distinguish one from the other; and if the jury of an Electrical Exhibition were confronted with a new dynamo they would find considerable difficulty in guessing its output, and for what purpose it was best suited. It has been

Digitized by Google

shrewdly observed that in Germany, dynamos have been built to suit the steam-engines, and in England steam-engines have been designed to fit the dynamos. So far, the dynamo will lend itself to moderate adaptation; but setting aside the difference between bi-polar or multi-polar machines, as depending largely on mere size; and speed and output, as mere details of winding, the dynamo does not allow of any such varieties for special purposes as we find in the steam-engine. The cylindrical armatures of CROMPTON and SIEMENS differ in appearance from the disc armatures of SCHUCKERT and GÜLCHER; but no one claims that any particular shape presents peculiar advantages for a given piece of work.

Closely allied to dynamos we find that motors are to some extent at a disadvantage compared with steam-engines in adaptability. It may be said that a motor consists only of an armature and a set of magnets, and that many changes cannot be rung on these. If we take one class of work for which steam-engines are often used, that of pumping water, we find the beam engine in use for the heaviest work, reciprocating engines specially designed without cranks for direct horizontal pumps, and high-speed engines differing altogether from the others for driving centrifugal pumps. But when we turn to electric motors for the same work we find no sign of adaptability. Each maker has three or four sizes of motor of the ordinary stock pattern, and he gears it to a three-throw or other pump with gear wheels or belt. This seems to be essentially un-English; and as we are conscious of the fact that the motor is not easily altered, the pump ought to give way. Seeing that the efficiency of a motor is intimately connected with its speed, the first idea, obviously, is to run the pumps faster and make them proportionately smaller. But hydro-dynamical difficulties of eddies and friction forbid this. Reciprocating motors are at present out of the question, seeing that they are urgently wanted for rock-drills, and have not responded to the call. The centrifugal pump, again, is not always applicable, as it needs charging, and a foot valve is often a nuisance. Hundreds of rotary pumps—most of them would-be rotary engines—have been invented; and some of these, especially those of the Root type, might be driven direct from fast-running motors. It is possible that alternate current motors will be more accommodating; and now that electrical engineers are something more than electricians, they may perhaps find that these motors can be more readily altered to suit the machinery than *vice versa*.

COMMUTATORS.—II.

BY F. M. WEYMOUTH.

(*Continued from page 246.*)

Now, though the difference of potential between adjacent segments may be slight, yet this varies from a minimum at the plane of commutation to a maximum at the sides of the commutator, in a plane at right angles to the plane of commutation. For assuming the plane of commutation to be vertical, and so the brushes at top and bottom, and the segments approximately in the same plane with the coils with which they connected, those segments at the sides connected to coils lying horizontal are collecting potential at a maximum rate; while the vertical segments at the top and bottom are connected to coils which are generating practically no potential. As regards drum-winding, this point was made clear in the article already alluded to, which appeared in *The Electrician* for July 19, 1889. The reasoning would be very similar in reference to Gramme-winding. But in consequence, the insulation between the segments must be sufficient to withstand this maximum difference of potential that occurs at the sides half way between the brushes. On the question of insulation, however, that between the bars and the substructure requires special attention; for there is the difference between the whole potential of the machine and the zero potential in the substructure to deal with. Here the insulation may be an eighth of an inch or more in thickness, and may consist of vulcanised fibre, mica, asbestos, or other material. Between the segments, it may be mentioned, mica is specially suitable owing to its natural cleavage, which allows of its easily being split into the very thin sheets required. Moreover, it is hard and well adapted to resist the compressive strain brought upon it, and so, with the segments, help them to form a solid mass compact together.

Now, while on this subject of insulation, and inasmuch as the substance commonly known as "fibre" is so largely in use for this purpose, it may be of interest perhaps to add some remarks concerning it, for which we are indebted to a somewhat complete *résumé* on the subject by manufacturers of this material. Vulcanised fibre is produced by chemically treating specially prepared vegetable fibre, whereby the exterior portion of each separate filament becomes glutinous. While in this condition, the whole mass is consolidated under heavy pressure, and rendered practically homogeneous. The chemicals are then extracted, and the mass is manipulated, rolled, pressed, and cured by various methods. These operations being of an extremely delicate nature, liable to vary with different conditions of atmospheric moisture and temperature, it requires great skill, care, and experience, as in many other manufactures, to produce uniformly good results. Besides possessing its well-known qualities of strength, elasticity, and durability, this material has the further qualities of not being soluble in any ordinary solvent, and is not injured by contact with petroleum or any of the animal, vegetable, or mineral oils. It does, however, which it is important to note, *absorb water*, either hot or cold; though it is not injured thereby, merely swelling when wet, and resuming its original size when dry again. Such absorption taking place would, of course, be fatal to its quality as an insulator. The vulcanised fibre is made in two qualities, "hard" and "flexible;" though for purposes of insulation the hard quality alone is applicable. A peculiarity is that this substance is produced only in sheet or tube forms. It will not mould; hence all objects to be made from it require to be cut out of either of these two forms, whichever may be the most suitable. The sheets, in size about 40in. by 60in., vary from $\frac{1}{50}$in. to $1\frac{1}{4}$in. thick, and are supplied in three colours, red, grey, and black; while the tubes, produced in lengths approaching two feet, have a thickness of shell not exceeding half an inch. It appears that these latter cannot be manufactured of less than $\frac{5}{16}$in. inside diameter, and the thickness, moreover, is proportioned somewhat to the diameter in the small sizes. Being rolled perfectly true and straight, with a good finish, they may be cut off into washers, or be used in lengths for enclosing and insulating bolts, and so forth. Having no grain, this material may be worked into all manner of shapes. Its specific gravity is about 1·3, and a cubic inch weighs about four-fifths of an ounce.

Vulcanised fibre, originally imported from America, has been put on the market in England and the Continent as an insulator, and having some insulating qualities, and being easily worked, has been very generally adopted. In this connection, however, we may give a table of specific resistances, compiled from measurements taken by Profs. Ayrton and Perry, and which we quote from *Uppenborn's Electrical Calendar*.

Vulcanised fibre	$1{\cdot}2 \times 10^6$	megohms	(B.A.)	at	20°C.
Mica	84·0	„	„	„	20°C.
Gutta-percha	450·0	„	„	„	24°C.
Shellac	9000·0	„	„	„	28°C.
Hooper's vulcanised India-rubber	15000·0	„	„	„	24°C.
Ebonite	28000·0	„	„	„	46°C.
Paraffin	34000·0	„	„	„	46°C.
Glass	Still greater.				

From the above it will thus be noted that fibre ranks last as an insulator. Now, with the *India-Rubber and Gutta-Percha, &c., Trades Journal* (May 9, 1892) as our authority, we there find an account of some experiments made as to the specific resistance of vulcanised fibre by Mr. Eugen Müller, of Berne, the original of which appeared in the *Elektrotechnische*

Digitized by Google

Zeitschrift (February 5, 1891).* The liability of fibre to absorb moisture has already been intimated. To how great a degree this liability extends, however, will be made clear from the following tabulated results of these experiments. It is to be observed that these were made under three different conditions. Firstly, the fibre was previously thoroughly dried by being enclosed in an exsiccator for several weeks; secondly, experiments were made after its exposure for 24 hours only to the by no means damp atmosphere of the laboratory; and, thirdly, after exposure for several months. Results with walnut wood are also included. (Ω L = Legal megohms.)

Specific Resistance (at 15°C.) per Cubic Centimetre.

—	Dry.	Exposed 24 hours.	Exposed several months.
	A.	B.	C.
1. White vulcanised fibre	$2,500 \times 10^6$ Ω L.	200×10^6 Ω L.	14×10^6 Ω L.
2. Different kind ,,	3,300 ,,	1,080 ,,	22 ,,
3. Light brown ,,	7,400 ,,	580 ,,	18 ,,
4. ,, ,,	12,400 ,,	1,002 ,,	54 ,,
5. Red ,,	16,500 ,,	245 ,,	10 ,,
6. Black ,,	20,500 ,,	2,000 ,,	68 ,,
7. Red ,,	35,400 ,,	3,250 ,,	54 ,,
8. Brown ,,	48,500 ,,	3,800 ,,	26·3 ,,
9. Ordinary walnut wood	99,000 ,,	2,870 ,,	53 ,,
10. ,, ,,	49,500 ,,	21,000 ,,	572 ,,
11. Paraffined ,,	∞	$620,000 \times 10^6$,,	3,690 ,,
12. ,, ,,	∞	$185,000 \times 10^6$,,	11,080 ,,
13. ,, ,,	∞	11,700 ,,	1,380 ,,
14. ,, ,,	∞	∞	830 ,,

It will thus be seen that though fibre, when perfectly and absolutely dry, has decided insulating qualities, it rapidly deteriorates in this respect with exposure. The loss, in fact, is tremendous, even in the first 24 hours. But in the humid climate of England, wherewith by far the greater part of the year the atmosphere is damp, the first two columns in the table would with the better reason be considered as appertaining to a condition of things contrary to general experience. For safety, the last column (C) is the one on which calculations should be based. We here find the specific resistance ranging from 10×10^1 megohms (L) for one specimen of red fibre, to 68×10^6 megohms for a black specimen.

The means of the results, however, are given as follows:—

White vulcanised fibre	about	18×10^6 Ω L
Brown ,, ,,	,,	26×10^6 ,,
Red ,, ,,	,,	32×10^6 ,,
Light brown ,,	,,	36×10^6 ,,
Ordinary dry walnut wood	53 to	572×10^1 ,,
Paraffined ,, ,,	530 to	$11,000 \times 10^6$,,

* Referring to this article Mr. W. Courtenay, President of the Vulcanised Fibre Company, writes to point out the rapidity with which ebonite or vulcanite (even when it is of the best quality, which is seldom the case) deteriorates with age, whilst vulcanised fibre actually improves, and after eight or ten years has been found in a better state than when first put in. Moreover, ebonite or vulcanite is almost always adulterated, and in time becomes perfectly perished, and its only claim to being considered an insulator lies in the fact that it is waterproof. Mr. Courtenay entirely denies that vulcanised fibre contains either jute or oxide of iron, as asserted by Herr Müller. All Herr Müller's figures giving comparisons with paraffined wood are, says Mr. Courtenay, quite irrelevant. As everyone knows, paraffin is one of the best non-conductors, and wood being exceedingly porous, the tests given refer in reality to the paraffin, and not to the wood. It is not to be denied that ebonite and vulcanite when pure (which they seldom are) have a higher resistance against high potentials than fibre. Against this must be balanced the mechanical weakness to which they are liable. Herr Müller is aware that the hygroscopic properties can be entirely done away with by giving it a coating of shellac or other watertight varnish, whenever circumstances would otherwise allow it to absorb moisture. Mr. Courtenay states that it is by no means certain that Herr Müller had got hold of genuine specimens of fibre, as many imitations of the genuine article had been produced. In answer to this Herr Müller, in a later issue of the *Elektrotechnische Zeitschrift*, states that the specimens of fibre tested were obtained from the sole agent of the Patent Vulcanised Fibre Company, Herr Wilfert, of Cologne. To this the latter replies that he has only supplied Herr Müller with a small sample of fibre, and that nearly two years ago. He also says that since the Vulcanised Fibre Company supply only one sort of fibre, whilst Herr Müller gives the results of tests on eight different varieties, there must be an error in supposing that the material experimented on was prepared by the Vulcanised Fibre Company.—[ED. *E.*]

In the first table we quoted it will have been noticed that the specific resistance of mica was given as 84×10^6 megohms (B.A.), at 20°C. This is considerably better than any results with exposed fibre, though by no means high as compared with the other insulating substances that follow it in the table.

It is obvious, however, that the whole question of insulation is bound up with the consideration of what is practicable and practical under any given conditions. Thus, in the case of commutators, with which we are more immediately concerned, mica, from its natural cleavage and hardness, is eminently suited for putting between the flat sides of the segments. For this purpose, therefore, it has been largely adopted. If we consider the various substances that are used generally for insulation, such as glass, porcelain, paraffin, ebonite, vulcanite, India-rubber, gutta-percha, besides mica, fibre, and so forth, we find none of the first named are applicable for use in commutators—or, at least, are not used to our knowledge. India-rubber and gutta-percha are too soft; ebonite and vulcanite are too friable, and wanting in strength; glass and porcelain have a certain strength; and though one may be tempted to look at these, the practical difficulties of adapting them to a fit would be great, besides the question of their extreme brittleness, and liability to chip, crack, and break. In a commutator, the insulation has to form part of the general structure, and has to take strain in common with other material used. This at once limits the substances that are applicable. For the necessary strength, therefore, together with practicability of working and other qualifications, we find ourselves more or less confined to vulcanised fibre and mica, though asbestos and other materials have been adopted.

Now, the excessive hygroscopic properties of fibre, to which we have been drawing attention, and which interfere so largely with its quality as an insulator, cannot unfortunately with any success be diminished by paraffining. For on account of its very inferior porosity, the temperature of the paraffin has to be raised very high (about 180°C.) to make it penetrate; and at this heat the fibre decomposes with effervescence, becomes brittle, and is rendered perfectly useless. Other drawbacks to fibre, however, are that it swells with absorbed moisture, and warps with heat; and commutators are liable to get warm. It is thus for these various reasons that some firms now are abolishing vulcanised fibre altogether from their commutators, and are using mica throughout. We hence propose now to give our attention more particularly to this material, and its adaptability for use in commutators—for the cones especially.

Touching briefly on the sources whence mica comes, it may be stated that it is found and mined, among other places, in New Zealand, Australia, Canada, Bengal, Madras, and Ceylon. There are various kinds of mica, and the term is applied to a group of crystalline rocks having the peculiar laminated structure well known. While a small specimen may easily be sliced thin through the cleavage with a pocket knife, on the edge it is about as hard as slate. Though it is found in slabs sometimes two or three inches in thickness, it cannot be worked like slate, nor even as though it were hard wood or soft metal. When required of any particular shape, size, and thickness it is necessary to build it up to the approximate dimensions of thin slices, separately worked, and all cemented together. The mass thus built may then be finished off by subsequent tooling. At the recent Electrical Exhibition at the Crystal Palace there were two exhibits of this substance, in the gallery, by Messrs. F. Wiggins and Sons, and Messrs. Wake and Sanders. In both of these there was a plentiful display of mica strips cut for use between the segments of a commutator. The former exhibitors, however, added two mica rings built up in the manner described, which were ready prepared for turning down into cones for commutators. These were to be observed in a case containing various very fine specimens of machined work, placed round the foot of a column of turned mica, which latter was doubtlessly unique in the Exhibition, as showing what can be produced with this material with proper knowledge and skill in its manipulation. Reverting to the rings, however, these are by no means wanting in strength. For, besides being hard on the edge, mica is also tough. A thin sheet will bend considerably before breaking. But

Digitized by Google

unless built up in the manner described, it has no great strength to resist parting in the cleavage. Some firms build up their own rings, though, as intimated, they may also be had from the makers, leaving only the turning to accomplish. From a practical point of view indeed, this latter course would probably be generally necessary, inasmuch as very heavy pressure is required for making the rings; those at the Exhibition for instance, though only about 8in. in diameter and $\frac{3}{4} \times \frac{3}{4}$in. in section, requiring no less a pressure than 175 tons. But in this manner cones may be obtained of sufficient strength, and as regards insulation and other qualities, considerably superior to vulcanised fibre.

Having now thus reviewed some of the different points that occur in connection with the design and construction of commutators generally, we may proceed perhaps with advantage to the consideration of definite examples. In so doing, it may be helpful to adopt some kind of classification. Thus a general division may be drawn between those designed to give the greatest depth of wear for the brushes, and those in which shortness of length has been made a special object. Figs. 3 to 6 herewith illustrate designs of the first-class, each showing

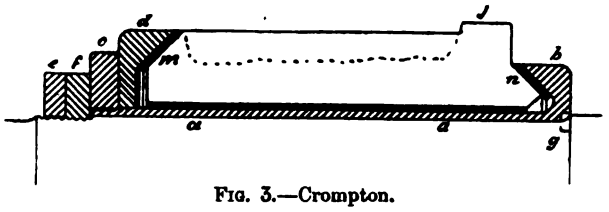

Fig. 3.—Crompton.

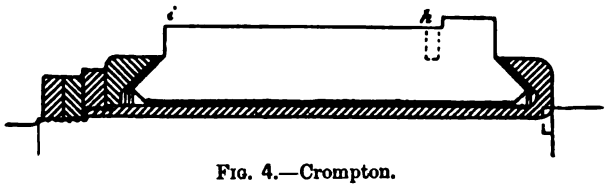

Fig. 4.—Crompton.

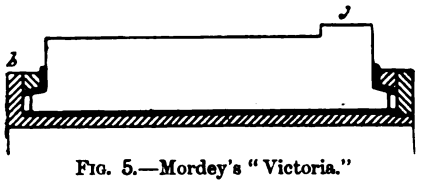

Fig. 5.—Mordey's "Victoria."

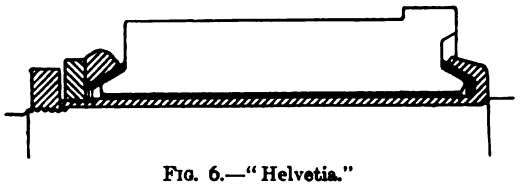

Fig. 6.—"Helvetia."

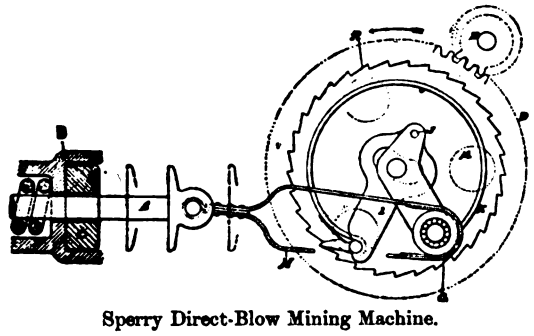
a longitudinal section through the upper half of a commutator only, similar to the upper half of Fig. 2, as with other figures that follow. Figs. 3 and 4 show two forms of commutator as made by Messrs. Crompton and Co., Limited. Fig. 5 is that of Mordey's "Victoria" dynamo; and Fig. 6 shows the commutator of the "Helvetia" dynamo constructed by Messrs. Alioth and Co., of Basle. It should be mentioned, however, in reference to these and succeeding figures that they are not scale drawings from specific examples; and though suited for the purpose of this article, no guarantee is intended that they all illustrate present day practice. Few parts of a dynamo probably are more affected by change than the commutator; and it is our purpose to discuss the reasons that lead to such changes, rather than merely to illustrate ultimate results. Now, the leading principle of all these, it is to be observed, is that of endurance. For there is no limit to the depth to which the bars may be worn down. They may in fact be worn right through—an occurrence which is not unknown; though allowing a commutator to run so long instead of renewing at an earlier period is perhaps scarcely commendable. This is, however, a leading point in these designs. Regarding them more closely, we note that they are all mounted on a sleeve or bush *a a*, which in Figs. 3, 4 and 6 has a mushroom head, *b*. In Fig. 5 the head is flat, and is placed at the contrary end to that where the shoulder *j* for the lugs occurs, as compared with the other figures. The segments are held on by a nut and washer *c d*: and in Figs. 3 and 4, the whole commutator is held on the shaft by a nut and lock-nut *f e*. In Fig. 6 only one nut is used for this latter purpose. The solid black represents insulation. Now with regard to Fig. 3, it will be noted that the washer *d* is of the same diameter as that of the combined segments. Thus it differs from the other designs in that these latter have a clear shoulder at the left end, as shown lettered *i* in Fig. 4. It may perhaps be said, without its being stated as a set rule, that Fig. 3 is more especially suited for small sizes. For this, referring to the nuts and washers, would be on the general principle that parts should never be too small absolutely. On a large scale certain parts might be minute in proportion to the whole, but not so absolutely—or in other words—to the size of a man. The same parts on a smaller scale would need to be of increased size in proportion to the whole, to avoid being too small absolutely. Beyond this consideration, however, a clear shoulder as at *i* allows of an unhampered peripheral surface for wearing down. A groove turned at the other end as shown dotted at *h*, Fig. 4, leaves a surface clear at both ends. In Fig. 3 the dotted line shows how the wear is confined and hampered at both ends, and illustrates the difficulty, if not impossibility, of keeping the wear even all along, so as to avoid sparking. The surface *i h* in Fig. 4 has not these difficulties. In a patent for this groove *h* taken out by Mr. J. W. Easton, of New York, it is recommended that it should be kept filled with some easily removed insulating material, to prevent its filling with metal dust from the wear of segments and brushes, which might otherwise cause short circuits between the bars. Though familiar with the idea of the annular slot some time before the date of this patent, we are not aware to what extent, and with what success, this method has been adopted in practice.

(To be continued.)

THE SPERRY DIRECT BLOW MINING MACHINE.

In a Paper on Electricity in Bituminous Mining read before the American Institute of Electrical Engineers, by Mr. E. A. Sperry, a reciprocating mining machine is described. Mr. Sperry



Sperry Direct-Blow Mining Machine.

has gone back to an ordinary high-speed motor, and obtains a reciprocating motion by an ingenious mechanism. This is described in his Paper in the strange dialect of the American language which is adopted by patent agents in the United States. We reproduce the diagrammatic illustration, but have translated the description. The reciprocating shaft A carries the mining tool at one end, not shown in the illustration. A strong spiral spring B drives the shaft forwards, and the electric motor draws it back. A buffer or cushion C is provided to take the shock when the tool is not brought up to the work. The spring gives an initial pressure of 500lb. A link or slotted connecting rod H is pinned to the end of the shaft A, and is retracted against the pressure of the spring by the crank pin G. This crank is mounted loose on the shaft. An arm I is pivoted at *s* to a lug on this loose crank, and carries a pawl which engages in the internal ratchet teeth of the wheel D. This arm is connected to the crank by a long hoop-shaped spring K. When in the

Digitized by Google

position shown in the illustration, the motor, which is kept continually running, drives the wheel D in the direction shown by the arrow, and its motion is transmitted by the ratchet tooth, pawl, arm I, to the crank G. Thus the shaft A is drawn back by the link H until the crank arrives at the dead centre M. As soon as this is passed, the powerfully-compressed spring B drives the shaft and tool forward, giving the working blow, and drawing the crank round much faster than the ratchet wheel. The tool when at work does not, of course, make the full outward stroke, but is brought up at some such position as A. The crank is at that moment at the position shown by the dotted circle *n*. The link H being slotted, there is nothing to stop the crank, and it is carried forward by its momentum to a corresponding position on the other side of the centre, where it is stopped by the link. The ratchet wheel being in continual motion, the pawl engages, and winding-up is recommenced at once. From 160 to 225 strokes are made in a minute. It is stated that "the mean effect of this type of machine is 935lb. when allowed to strike the cushion," and when striking the work at a distance of one inch from the cushion gives "1,000lb. mean effect." The mean effect in air machinery employed for the same purpose is between 400 and 450lb., a 3¾-in. cylinder being the largest employed. The current is 10 amperes at 220 volts; the shaft and tool weighs from 100lb. to 150lb. It is found that the whole machine must be fairly heavy to take the recoil. We have recorded numerous attempts to construct direct acting solenoid machines for producing a reciprocating motion, but no really successful one has yet appeared. Much current is generally wasted in starting the armature at each end of the stroke. In a steam cylinder nothing is wasted in imparting a high initial pressure during the period at which the piston is at rest or is just beginning to move, for no steam is expended. But in a magnetic reciprocating machine, a steady flow of current must take place during this period, and the current will probably be greater than at other periods because the armature is more or less stationary.

TELEPHONIC AND CONTINUOUS-CURRENT CIRCUITS.*

BY A. PALAZ.

At the beginning of the telephonic industry, when telephone exchanges were being inaugurated, the exquisite sensitiveness of the microphone and telephone called forth every one's admiration. If this feeling has not diminished with the *sarant* it has certainly completely disappeared so far as the practical man is concerned; he would vastly prefer more powerful microphones and less sensitive telephones. Indeed, we must attribute the fact that long telephone lines are never completely silent to the great sensitiveness of that instrument. Such lines are always the seat of excessively weak variable currents, which make themselves felt in the telephone in the shape of various noises more or less intense, but which it would be otherwise difficult to detect even with the most sensitive measuring instruments. These parasitic currents are due to a variety of causes; and it is no easy matter in any given case to assign each its proper relative value, a fact which greatly complicates the investigation of the methods to be adopted in order to completely suppress the disturbances on telephone lines. On lines which complete the circuit through earth the influence of terrestrial electrical phenomena is especially noticeable. Any telephonic wire which goes to earth at either end is subjected to all the variations of the earth's potential, produced either by meteorological or electro-industrial causes. It is, therefore, difficult to find on a single-wire urban system a line on which one cannot hear the telegraphic signals passing along the wires which terminate at the town telegraph office. The successive emissions of current give rise to undulatory variations of the earth's potential, and these variations reach the telephone line by the earth plates, and the latter becoming polarised give rise in their turn to variable currents resulting in parasitic noises. Atmospheric influences are also of great importance; the variations in the electrical condition of the air are reproduced on the telephone line in the shape of variable currents (earth currents). In times of storms, for instance, when the atmospheric electrical discharges suddenly upset the atmospheric electric equilibrium, telephone lines are the seat of powerful parasitic currents, which materially greatly augment the disturbing noises which are then particularly irregular. Lastly, we ought to mention the currents induced by the swaying to and fro of the wires in the magnetic field of the earth under the action of the wind. These last telephonic disturbances are of meteorological origin and impossible to completely avoid. But the same cannot be said for the parasitic noises due to the neighbouring wires traversed by variable currents, telegraphic or industrial; this action may either be due to induction or to stray currents from the other lines arising from bad insulation. This is the explanation usually given of the disturbances produced by industrial currents in telephone lines.

Owing to the great development of industrial electricity the stray currents from industrial circuits have become more and more the principal disturbing element of telephonic traffic. Lighting and telephone circuits are being developed together, and they are mixed up with one another. Telephone lines and their earth plates are in the immediate vicinity of wires connected to electric lighting apparatus, so that the slightest leakage to earth from an industrial circuit finds an easy path into the telephone lines. All the variations of consumption on the industrial circuit are, therefore, felt on the telephone circuit, in which we may note the variations in the output of the machines by the variations in the parasitic disturbances.

In the case of continuous-current industrial currents, and in this article I shall only consider such, we may assume as a fact demonstrated by the experience gained in numbers of important works, that the only disturbing action of the industrial circuits upon telephone circuits arises from leakage to earth from the former. Induction only plays a very modest part. This view is shared by those who have been at the pains to verify it experimentally. To suppress all disturbance on a telephone circuit the industrial circuit must be perfectly insulated from earth in order to prevent these leakage currents, which give rise to sensible differences of potential between the earth plates of the telephone circuit, causing powerful parasitic currents to traverse it. This has been very well understood in those countries where the telephone is omnipotent as part of the administrative gear of the State. Thus the elaborate rules and regulations drawn up by the Swiss Telegraph Administration, under the law relating to the erection of telegraph and telephone lines, contain a clause specifying a minimum insulation for an industrial network, and makes it obligatory to test the insulation of every house installation before it is connected up. It is easy to obtain a good insulation on an electric lighting network; it is, indeed, necessary to the good working of the plant. Under these conditions a single-wire telephone system and an electric lighting continuous-current network can exist simultaneously without telephonic business being very much troubled.

It is altogether different when we come to the simultaneous existence in the same town of a telephone exchange and a system of electric tramways to which the current is supplied by wires. Tramways of this description may be divided into two categories: those in which the feeding circuit is entirely metallic, and those in which the earth or rail is used to complete the circuit. In the former case the disturbances experienced on telephone lines are largely due to the currents straying to earth through the motors, car frame and rails; a result which it is impossible to avoid. That this is really the cause is confirmed by the fact that the disturbance increases in strength in wet weather, when the insulation of the line and motors falls. At Montreux, for instance, where the 11-kilometre electric tramway is on the two-conductor system, with hollow overhead conductors and a sliding shuttle-shaped contact, parasitic noises due to the tramway currents are frequently observed. It is in fact quite easy to follow the course of the cars, and to note their speed, stoppages and startings. In the second case the action of the tramway current upon the telephone circuit is direct in the sense that the return of the current through the rails and earth produces differences of potential between the ends of the telephone lines near the tramway, and thus large parasitic currents are generated. These disturbances are much greater than the others, and it is very difficult to diminish them sufficiently not to interfere with the telephone service.

We can therefore assume, without fear of contradiction, that a telephone service is practically and commercially very difficult, if not impossible, in the case of a single-wire system existing in conjunction with an electric tramway system having a rail return.

There are two remedies: the tramway may be changed from the rail-return system to the complete metallic circuit, without touching the telephone system; or we may let the tramway alone, and change the telephone network into one on the complete metallic circuit system. There can be no hesitation in saying which course should be taken: the first sanctions the *status quo* and the stagnation of telephony; the latter is an enormous improvement in telephony, the most important, indeed, which remains to be carried out at the present moment. And while effecting an improvement, this solution of the question restores complete independence both to telephonic and industrial circuits. It should,

* From *L'Électricien*.

Digitized by Google

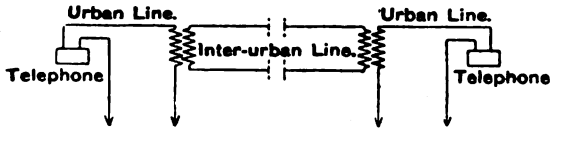
therefore, alone be allowed where a system of electric tramways is laid down near a telephone system.

Moreover, the introduction of twin wires should be considered, quite apart from all external disturbing causes, as an absolute necessity. The public should not cease to demand this improvement, for this supreme fact must not be lost sight of; it is impossible to get perfect telephonic transmission on a circuit of which the earth forms an integral portion.

This conclusion follows indeed from what has been said before, but it is strengthened by the following considerations called forth by the exigencies of interurban telephony. If the telephone did not at the commencement overstep urban limits it now no longer keeps within them. The telephone becomes every day more important as a means of long-distance interurban communication. A study of the statistics of interurban telephony shows the growing importance of this branch of telephony, both as regards the number of communications and as regards the receipts. We may boldly predict without fear of contradiction by events that the second decade of the telephonic era will be specially devoted to the development of long-distance communication; the first decade having witnessed the development of urban communication. The limits of this article preclude a proof of this assertion from the statistics of the countries in which the telephone service is most highly developed, namely, Sweden, Switzerland, and Germany.

Now interurban telephony is impossible without complete metallic circuits, at any rate in the case of long-distance lines; in fact, metallic circuits alone give us silent lines, and allow us to erect lines with many circuits. This last desideratum is of the utmost importance from the economical point of view. In Switzerland, for example, single-wire interurban lines have up till now been erected, the inconvenience due to parasitic noises being passed over. It has been necessary to run these lines along routes having no telegraph wires in order to avoid the induction from them. But at the present moment the majority of these circuits are too crowded, and the following dilemma arises:—Shall the new lines be run along roads not yet used, taking a circuitous route, or shall they be double wired? The first solution is evidently impracticable, since in the end the entire country would be covered with a serried network of telephone lines, both costly to maintain and to watch; and the prime cost would soon be higher than that of double-wire multiple-circuit lines run on the old poles.

Interurban circuits being on the twin-wire system, it necessarily follows that the same thing must be done for the town circuits, in order to avoid a double translation. Single-wire urban lines have to be joined to twin-wire interurban lines by means of translators, which are simply transformers, the secondary circuit of which is interpolated in the interurban line, the primary being in the subscriber's earth-completed circuit. The connection between two subscribers and an interurban line is effected, in fact, in the manner shown in the accompanying diagram. There are, therefore, two



transformations of the telephone current; and as each causes a deformation and a weakening of the electrical waves, the result is a distortion of the voice and a diminution in the volume of sound. Hence this device has given but indifferent results in practice, and absolutely cannot be considered as a solution of the problem of connecting single-wire urban to double-wire interurban lines. The only truly satisfactory solution is to adopt nothing but complete metallic circuits for all telephonic transmission.

Yet another decisive argument militates in favour of this improvement. Owing to the continual augmentation in the number of telephone subscribers the overhead telephone networks are becoming more and more crowded, so that in towns of any commercial importance telephone engineers are face to face with the absolute impossibility of connecting up fresh subscribers to their exchanges. It is necessary, therefore, to have recourse to underground telephone wires and to replace overhead wires by subterranean cables This change is also generally desirable in the case of the central portions of aerial systems, where the crowding of wires is often intolerable and in winter even dangerous, owing to the frequent breaking of the wires by the action of cold and rime. The fracture of a single wire frequently results in that of the neighbouring wires upon which it falls, and this naturally causes interruptions which it takes a long time to restore.

But multiple-conductor telephone cables do not give satisfactory results if used with single-wire circuits. Cables of this kind consist of a number of insulated wires covered with a conducting sheath, lead in the Berthoud-Borel and metallic foil in the Felten-Guilleaume cables, the whole being cabled together. The metallic sheathing of all these wires is connected to earth, and its object is to completely suppress mutual induction between the wires of the same cable. This result is only approximately obtained. When these underground lines become somewhat long the mutual induction of the neighbouring wires is far from negligible. On this account, it is no use thinking of employing these cables for extensive telephone systems. Recourse must be had to complete metallic circuit cables, in which the two wires of every circuit are twisted together so as to completely eliminate their mutual inductive action. Cables of this kind alone permit the establishment of extensive telephonic networks in a manner which shall assure a satisfactory service. This fact has, indeed, been recognised by the Swiss Telegraph Administration, which has substituted in some cases single-wire cables for cumbersome overhead wires, and which now seems anxious to adopt double-wire cables. Thus at Zürich at the present moment they are laying down several kilometres of underground cables having 300 separate metallic circuits; this decision naturally involves the complete transformation of the telephone network into a twin wire network, and the authorities are proposing to do this.

All the desiderata of telephonic traffic are summed up in the formula—exclude earth and employ complete metallic circuits. This transformation of the telephone circuits will not be carried out without considerable expenditure; but it must come, since it is imposed from a purely telephonic point of view, and it will be the last step in the progress of telephone exchanges. It is to be remembered that at the dawn of telephony, engineers, struck by the marvellous sensitiveness of the telephone, said, "Anything is good enough for the telephone." Insulation and high conductivity wire seemed useless, but we have gradually come back from this point of view; and now the greatest care is betowed upon the insulation of the circuits and the conductivity of the lines. Single and double bell insulators have replaced the ordinary mushroom insulators which were first employed. Copper and bronze wires have been substituted for iron wires, while the joints are now carefully soldered, a precaution at first considered unnecessary. Indeed, we are all crying, "Nothing is good enough for the telephone." In any case. what has been said above shows that every telephonic system that uses earth as an integral part of the circuit does not fulfil modern conditions, and ought to be considered as defective.

The electrical monopoly of the earth, which the Telegraphic Administrations of certain States have assumed, should be considered as an encouragement to the spirit of routine. Commercial men of all countries should raise their voices against this contention, all the more extravagant since telephonists without exception anticipate the introduction of twin wires; it is absolutely necessary to insist upon this improvement in telephonic systems from the present moment, since the longer we wait the more difficult it will be to carry out the change, owing to its costliness. No multiple switchboard should be introduced into an exchange without the system itself at the same time being transformed, even where underground wires are used.

The complete metallic circuit being imposed upon telephonic exchanges by the necessities of their business, there can be no question of imposing upon electric tramway promoters the conditions that they should not employ the rails as a return. The single-wire method of construction is the only one which is suitable for tramways in the vast majority of towns, where small first cost and regular working are of first importance. A complete metallic circuit for tramways increases the first cost by 50 per cent. In the case of aerial conductors (which I am alone considering) it also complicates the system, the double trolley being a very difficult business, especially at crossings where it causes numerous breakdowns. To decree complete metallic circuits for all electric tramways is tantamount to depriving a large majority of towns of this mode of locomotion, where it would otherwise be possible, without taking into account the fact that the leakage current to earth would in spite of the double circuit always be sufficiently strong with telephone earth returns, as in the case of the Vevey-Montreux tramway, to interfere with other lines.

There can be no question, therefore, about insisting upon electric tramways employing metallic circuits in order to avoid the necessity of introducing the same on telephone lines. The use of the rails as a return for tramway currents is advantageous from a financial point of view; andit would be out of the question to forbid it, with the sole object of allowing telephone companies to persevere in mistakes fatal to good working. The earth return is advantageous from the technical point of view, inasmuch as it considerably facilitates both the construction of the lines and their working; crossings in particular are much more easy to carry out, and the appearance is less distasteful. The accumulation of conductors at the junctions and crossings are not so great, without mentioning the fact that the poles can be lighter and more elegant. From the financial point of view the advantages are still greater, since, in addition to the fact that the constructive facilities result in appreciable economy, the suppression of the return wire in itself constitutes a great saving. These conclusions hold good for subterranean conductor electric tramways as well as other lines. This is not tanta-

Digitized by Google

mount to saying that the electric tramway ought to be constructed without any precaution whatever. It is most important to secure good metallic contact between the rails in order to avoid sensible difference of potential between different points of the circuit. With this object it is good to lay along the rails a copper conductor making good contact with the rails at the fishplates. This method has given excellent results wherever it has been employed, as at Clermont-Ferrand and Sissach-Gelterkinden. The pole of the generator which is put to earth ought to be connected to this copper wire. This precaution is always necessary with earth return. The second precaution is good insulation of the line, which can be obtained with special oil or deep double bell insulators. Good insulation is necessary, by reason of the leakage which might arise without it, between the iron pillar and the conductor which it supports. Beyond this it is difficult to see what conditions can be imposed upon the electric tramway promoters.

There was at one time talk of employing a single large return wire as a common return for all the wires of a telephone exchange. Some satisfactory experiments have been made; and at the time when this idea was mooted I submitted the matter to calculation, and arrived at fairly satisfactory results, but which I have been unable to confirm by direct experiment. In spite of this, however, the employment of a common return for a telephone exchange cannot be generally recommended, owing to the complication of working which it would entail, a complication altogether out of proportion to the slight improvement which would be obtained in the working.

All that has been said seems to show sufficiently well that the following rule should be the basis of modern telegraphy:—All telephone lines should be constructed with complete well-insulated metallic circuits, and the earth should be completely excluded. When these conditions are fulfilled the disturbances produced by continuous electric lighting currents or the currents of electric tramways are completely annulled, a result which can only be arrived at in this way.

THE ELECTRICAL TRADE SECTION AND THE CHICAGO EXHIBITION.

The following circular letter has been sent to members of the Electrical Trade Section:—

LONDON CHAMBER OF COMMERCE,
Botolph House, Eastcheap, London, E.C., July 17, 1892.

Dear Sir: As you will no doubt observe from this week's issue of the Trade Papers, Mr. W. H. Preece, of the General Post Office, attended at the meeting of the Electrical Trade Section of this Chamber on Friday last, and gave reasons why the Section should endeavour to co-operate in the organising of a representative British Electrical Exhibit at the forthcoming Chicago Exhibition. The Society of Arts, as you are aware, are acting as the British Royal Commission for this Exhibition, and we are informed by Mr. Preece, as representing the Electrical Section on that body, that while other industries will send to the Exhibition the most magnificent display ever sent by this country to any home or foreign Exhibition, the electrical industry has up till now been an exception to the rule, and the articles to be exhibited are not considered to be anything like an adequate representation of the advancement which has been made in the application of electricity in this country during recent years, especially, too, as we believe the amount of capital invested in England has enabled developments to be made which have not as yet been equalled in any other country. For your information, I enclose a list* showing the firms proposing to exhibit, the articles to be exhibited, and the space occupied.

Hitherto, there has, we believe, been a disinclination to exhibit at Chicago, probably from a feeling of resentment in the first place to the McKinley tariff, and secondly because, apart altogether from this question, to exhibit there is not likely to result in developing any further trade with the United States. In regard to the first of these considerations, we would point out that if there were to be an entire absence of English exhibits, or even of electrical apparatus alone, visitors would seek for, and no doubt find, a reason for the absence of English exhibits in the McKinley tariff; but, as certain firms find it an absolute necessity to exhibit if they are to preserve the trade which they have already acquired with foreign countries, the question comes to be whether foreign visitors will not be entitled to regard the exhibits there as fairly representative of the state of the electrical industry in England. In regard to the second consideration, nearly all are agreed that the Exhibition will not be productive of any trade with the United States; but in view of what has just been said, is it not desirable, in the interest of British foreign trade in general, that the industry should combine to make a representative exhibit? Such an exhibit would impress foreigners with the progress which has been made in this country in electrical science, and might possibly result in inducing them to make application later, if need be, to English firms, instead of patronising nations who have created a better impression in consequence of a better display. Further, the various articles comprising the exhibit can be labelled prominently with the name of the makers, so that the exhibit will be personal as well as representative of the industry as a whole.

Mr. W. H. Preece suggests that this object might be accomplished by a certain number of firms combining as a syndicate to furnish a suite of rooms, and to have them decorated and lit up by electricity in the manner common to English houses. The expense would, of course, in this case be shared proportionately. If a response to this circular is received which would warrant our prosecuting this matter further, then the Chamber would make an effort to secure the co-operation of the Furniture and Textile Trade Sections in supplying furniture, carpets, curtains, &c., &c. In such an event the expense to each individual firm would, of course, be reduced proportionately. Mr. Preece has no doubt that the Royal Commission would be prepared to take charge of the exhibit, but possibly exhibitors would prefer to appoint some one to take charge of the exhibit who might be paid a commission on the sales.

Free space has been provided, and only 5,000 out of the 20,000 square feet provided for electrical exhibits has as yet been allotted. In order that we may know how far we are likely to be supported in endeavouring to carry out such a scheme as has been here indicated, I should be glad if you would fill up the enclosed form and return to me at your earliest convenience.—Yours faithfully, KENRIC B. MURRAY, Secretary.

[ENCLOSURE.]

(1.) Are you prepared to exhibit at Chicago on the lines indicated on the enclosed circular? (2) If so, what sum are you prepared to guarantee, it being understood that you would only be called on to subscribe proportionately, the proportion, of course, depending upon the number of firms coming forward? (3.) What would be the nature of your exhibit and the amount of space you would be likely to require?

* *See* p. 285 of last week's issue.

LEGAL INTELLIGENCE.

The Medical Battery Company v. Jeffery.

On Tuesday, at the Bloomsbury County Court, before his Honour Judge Bacon, the claim and counter-claim in the above-named action were heard. Mr. De Witt (barrister-at-law) appeared for the Company, and Mr. Lickfold (Messrs. Lewis and Lewis) appeared for the defendant.

The claim was £3. 5s., balance of £5. 5s., the price of an electric belt (Harness's patent) supplied by the plaintiff Company to the defendant; and the defendant, by way of counter-claim, sought to have an I.O.U. for £3. 5s. delivered up to him, and the sum of £2 cash returned to him on the two following grounds:—First, that he was induced to buy the electric belt through misrepresentation; and, secondly, that there was no good consideration for the contract into which he had entered with the plaintiff Company.

The following evidence was taken:—

Mr. FREDERICK THOMAS SIMMONDS, examined by Mr. De Witt, said he had been in the employ of the plaintiff Company for nearly seven years. He had had great experience in fitting trusses and dealing with hernia and strains. The defendant came to their establishment on May 9th, and saw one of the receiving officers. He was shown to the witness's consulting room. He said he had a sprain which he thought might develop into rupture. Witness examined him, and said the hernia was incomplete. Witness recommended the electric belt in order to decrease the pressure, and to give a tonic to the muscles.

Cross-examined by Mr. LICKFOLD: Witness said he had been employed by the plaintiff Company for nearly seven years. He began treating hernia after he had been with them for about three months. Before being employed at Harness's he was engaged in commercial pursuits. He had studied hernia all his life; ever since he was nine years of age. His "commercial pursuit" before he was employed by the plaintiffs was that of salesman in Oriental furniture in the West End of London. He did not acquire much knowledge of the treatment of hernia in selling Oriental furniture. But after being in the plaintiff's employ for three months developed into a consulting person. He had assistance from others. He was now one of the consulting officers. He did not send for one of the medical attendants because in matters relating to hernia his practice was far beyond theirs. He did not think it necessary to consult them except in a very complicated and abstruse case—and then they generally left it to him. The belt sold to and worn by the defendant weighed between 2lb. and 3lb. It was a proper belt for incipient hernia. There was electricity in it. The patient did not require more electricity than he would get out of the belt. Witness on being asked to pledge his oath that there was any electrical current in the belt, said that he had no knowledge of electricity.

Mr. LICKFOLD, addressing the Court, said the defendant was a cashier in the Union Bank, and having, as he feared, ruptured himself, his attention was attracted to an advertisement calling attention to the Electropathic and Zander Institute, 52, Oxford-street, where medical advice was given gratis. He asked to see a medical man. He saw Mr. Simmonds, and told him he was suffering from rupture. Mr. Simmonds examined him, and told him he was not so suffering, and added, "You must have one of our belts, and that will set you right." The defendant was fitted, and took a belt costing £5. 5s. Instead of doing good, the belt chafed the skin and caused an eruption, and the illness was so aggravated that the defendant consulted a medical man, Dr. Rowntree. After going through the facts, Mr. Lickfold said he should produce evidence to prove that these so-called electric belts were nothing else than fraudulent impositions. People were inveigled into this trap, and belts, which were absolutely worthless, were palmed on them, and they were ashamed to proclaim their

Digitized by Google

folly by prosecuting the promoters of these impostures. But it was now time that it should be put a stop to. The learned gentleman submitted that there had been misrepresentation in this case, because Mr. Simmonds was not a qualified man, and because he misled the defendant by telling him that he was not suffering from hernia when he was so suffering. Then the defendant was entitled to have his money and I.O.U. returned to him, as he had not received any good and proper consideration for his money.

The defendant, Mr. D. JEFFERY, in examination-in-chief, said he was very pleased at being told he was not ruptured. He wore the belt for some time, and it gave him great pain. There was a downward pressure, and a lump formed in his groin—an external sore also formed. When he took off the belt he felt relief. He consulted Dr. Rowntree. He left off the belt entirely and wore a truss, which cost 12s. 6d. He was much better now. The doctor told him he was ruptured, and had been so for some time.

Cross-examined by Mr. DE WITT: Witness stated that he wore the belt for more than a week. He got so bad that when he moved he was in excruciating pain. He did not ask the price of the belt before it was fitted on, and had he known it was £5. 5s. he would not have purchased it.

Mr. WILLIAM GEORGE ROWNTREE, L.R.C.P., examined, said on May 23rd Mr. Jeffery called on him at his house. He examined him, and found that he was suffering from rupture. There was no doubt about the nature of his suffering. He had examined the belt, and he was of opinion that if it was fitted tight on a patient suffering from rupture it would aggravate the complaint. He had heard the defendant's evidence as to the swelling in the groin, and he thought that that swelling had existed for some time previous to witness seeing him. The belt would not be of any use to the defendant. He recommended a truss, and the patient was getting better.

Mr. T. E. GATEHOUSE said he was an electrical engineer. The belt in question had no electrical powers, and was utterly useless. As the belt was worn it never produced a trace of electricity. That morning he had made an experiment with the belt, so as to produce a small quantity of electricity. He took salt water, and moistened the two parts, and then he connected the copper and zinc with a galvanometer, and so he got a slight deflection of the needle of about 14 degrees. He then put the belt on his legs and on his arms, and the deflection was not in the slightest degree altered. That showed that when these belts were worn by any patient no electricity passed through the body in any way whatever, but only along the webbing of the belt and over the skin surface. Electrically these things were useless.

Cross-examined by Mr. DE WITT: Witness said that zinc and copper were used in generating electricity. The belt would produce no current at all as the defendant wore it. The circuit was not completed. He saturated the belt with salt water and then he got a small electrical current. He said there was a current if properly connected up, but the current would not go through the body—it was the webbing and skin and not the body which formed the internal circuit.

This concluded the evidence.

Mr. DE WITT contended that though there might have been an error in judgment on the part of Mr. Simmonds, there had been no wilful misrepresentation—such as according to the ruling in the case of "Peek *v.* Derry," would entitle the defendant to have his contract rescinded and his money returned. He also submitted that there had been no failure on the plaintiff's part to give the defendant consideration for his money.

His HONOUR, in giving judgment, said: In this case the plaintiff sued for the balance of the purchase money of an electrical appliance, and the defendant by his counter-claim said, "I want to get back the money which I paid on account, either on the ground that I bought it on the misrepresentations made to me by your agents, or on the ground of a failure of consideration." His Honour was of opinion that it was clear on the evidence that the defendant went to the plaintiff's establishment and asked to see a qualified doctor. That was uncontradicted. The defendant had shown that the gentleman whom he saw (the gentleman who called himself an "expert;" a gentleman without any medical education, or education in this matter, except having studied the best works on the subject since he was nine years of age), and when he asked for a truss, recommended him something which he said was better. The defendant had shown that this gentleman told him he was not suffering from rupture, but only from the beginning of rupture. I have no doubt from the evidence Mr. Simmonds said to the defendant: "I am happy to tell you you are not ruptured." But that was not the fact, the defendant was ruptured, as his Honour could not help believing from the evidence of Dr. Rowntree, who said: "From my observation, and from the symptoms described to me by the defendant, I am satisfied that the rupture had existed three months before I saw him on May 23rd." Then was the thing which the defendant received the thing which he asked for? His Honour would not enter into the merits of an electrical appliance which he did not understand. Mr. Gatehouse's evidence as to the electrical volume might be right or wrong—he did not know; but this belt was the thing put on the man when he was ruptured, and the man was persuaded to buy it upon the representation that he was not ruptured. He went for a truss. He was told, "You do not want a truss." This is a representation made by a man who had not taken the trouble to qualify himself, and who ought not to have made any representation at all. That was the representation which led to the contract, a contract without any good of any sort to the defendant, and it must be voided. There must be judgment for the defendant on his counter-claim, and his £2 must be returned to him.

Mr. LICKFOLD applied for costs on the higher scale.

His HONOUR refused the application. Judgment accordingly.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July* 2, 1892.

Electric Lighting at the Chicago Exhibition.—As announced in a former letter, the contract for lighting the World's Fair grounds was awarded to the Westinghouse Electric and Manufacturing Company. Mr. Westinghouse, through his individual efforts, secured this contract, taking it at a very low rate in sharp competition with the General Electric Company. At the time the bid was made Mr. Westinghouse agreed to furnish a bond for $500,000 to assure the authorities that the contract would be carried out. The first bond furnished was rejected, as it appeared on investigation that the Company furnishing the bond had just been organised with a capital stock of $500,000, and it appeared to the authorities that the Company had been organised for this purpose. It is now announced, however, that the bond is guaranteed by an indemnity bond signed by August Belmont, Charles Francis Adams, Brayton Ives, Marcellus Hartley, and George Westinghouse, jun.; this has been accepted as satisfactory. It is stated that the contract for the necessary wiring has already been placed by the Westinghouse Company, and that Mr. E. E. Keller has been placed in charge of the work. Mr. Keller resigned his position as assistant to Chief Barrett to take charge of this work.

Allotment of Space at the Chicago Exhibition.—The allotment of space in the different departments of the World's Fair began on July 1. Applications have been received for space in the electrical building covering twice the floor space at command, so that very few, if any, of the exhibitors will be given as much space as they have applied for. The authorities are about to carry out some tests of different styles of electric, steam, and naphtha launches for use on the lagoons in the Exhibition grounds.

Telephone Statistics.—The first publication of the Census Department of Statistics relating to the electrical industries has just appeared in the form of a special census bulletin. This refers to the telephone statistics of the country, and gives detailed comparisons regarding the cost and operation of telephones in 1880 and in 1890; one of the most interesting points noted in this publication is that while the gross earnings per subscriber have increased 12·75 per cent., and the gross expenses per subscriber have remained about constant, the net earnings per subscriber have increased 54·68 per cent. At the same time the aggregate dividends per subscriber have increased 123·04 per cent., and the surplus per subscriber has increased 5·63 per cent. The percentages of increase and decrease from 1880 to 1890 in those items of essential interest to the public are shown in the following summary:—

Summary showing Percentages of Increase or Decrease from 1880 to 1890.

	Increase (per cent.)		Decrease (per cent.)
Number of companies, firms, and persons reporting	—	...	64·19
Interest-bearing and profit-sharing investment	395·30	...	—
Interest-bearing and profit-sharing investment per mile of wire	—	...	29·34
Interest-bearing and profit-sharing investment per subscriber	5·30	...	—
Net earnings per mile of wire	3·60	...	—
Net earnings per subscriber	54·68	...	—
Number of exchanges	183·98	...	—
Miles of wire per exchange	145·57	...	—
Number of subscribers per exchange	64·86	...	—
Number of *employés* per exchange	—	...	12·50
Miles of wire	600·81	...	—
Miles of wire per subscriber	49·30	...	—
Number of subscribers	369·61	...	—
Number of *employés*	158·99	...	—

Railway Motor Tests.—One of the most interesting Papers read at the recent meeting of the American Institute of Electrical Engineers was that on railway motor tests, by Prof. G. D. Shepardson, of the University of Minnesota. The Paper contained a large number of very interesting results obtained by tests upon railway motors, using the two most common methods of regulation, namely, commutating the field and using a dead resistance. One of the most surprising features shown by the

Digitized by Google

curves which he exhibited was the violent fluctuation of current when something over 200 cars were in operation. It has generally been supposed that increasing the number of cars smoothed out the irregularities of the load diagram; but it appears that in this case the main ammeter indicated fluctuations from 1,400 to 2,700 amperes, while the greater part of the fluctuations were between 1,800 and 2,400. Prof. Shepardson also gave what is probably the first explanation of the phenomena known among railroad men as "bucking" of the motors.*

NEW YORK, *July* 8, 1892.

The Marking of Foreign Goods at the Chicago Exhibition.—Considering the fact that much interest has been aroused in England and other European countries concerning the recent order issued by Director-General Davis, of the World's Fair, to the effect that foreign exhibitors could not be permitted to mark their goods with the selling price, minus the duty, it will be a matter of considerable surprise that a circular has now been promulgated of an exactly opposite order. This circular should set at rest all doubts in regard to the privilege of marking the selling price of their goods by foreign exhibitors, both with and without the duty. The part of this circular which is of most interest reads as follows:—"Foreign exhibitors to the World's Columbian Exposition will be permitted to state upon placards attached to their exhibits the prices at which said products shall be sold at place of manufacture, and also the price in bond and out of bond, or exclusive and inclusive of the customs duties in Chicago." The letter states that the former ruling in this matter was a mistake, and is, therefore, revoked. This circular letter has been sent out to foreign consuls, and is to be given as much publicity as was given the former incorrect ruling in the same case.

The New York Rapid Transit Scheme.—The Supreme Court of New York State has approved the report of its sub-committee, authorising the Rapid Transit Commissioners to go ahead with the building of the rapid transit road which has been planned for this city. This ruling merely gives the Commissioners authority to proceed with their work, provided, of course, the necessary capital is forthcoming. The general outline of the proposed plan is already familiar to your readers. It contemplates the construction of an underground road in the form of an immense Y, the two arms being eight or ten miles in length, and the stem about four miles. In regard to the motive power to be used no specific arrangement was called for, except that the report limited the contractor to the use of one system, electricity or otherwise, not requiring combustion in the tunnel. Whether or not the progress of the work will be hindered by unexpected trouble in raising capital for the enterprise remains to be seen. It is rumoured that complications have already arisen, owing to projected improvements and extensions of the existing elevated railroad system. This would interfere, it is thought, very materially with the work of securing the necessary capital.

CORRESPONDENCE.

ELECTRIC LIGHTING IN SWITZERLAND.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We send you a few supplementary notes on details of the Geneva Central Station, published in your issue of July 1st.

At the end of 1891 the Société d'Appareillage Électrique and the electric works of Cuénod, Sautter, and Co., owners of the Thury patents, were united under the name of Compagnie de l'Industrie Électrique; and from this period the electric lighting of Geneva has received a good deal of development and improvement. There is only one difficulty opposing the further increase of the central station—the society is forbidden to furnish electricity as a motive power, since the distribution of water under pressure for supplying turbines is in the hands of the municipality.

At the central station of the island the dynamos are not driven by turbines taking their water directly from the river, but by the high-pressure service. The Compagnie de l'Industrie Électrique is completing the building containing the hydraulic plant, and known at Geneva as Les Forces Motrices, as an alternating-current central station. There is only a 50 H.P. alternator at work at the present moment. Two others, one of 100 and the other of 200 H.P., are to be erected as soon as possible. The transformers are enclosed in cast-iron boxes, fixed on cast-iron stands.

The forthcoming installation of Chevres, utilising the waters of the rivers Rhone and Arve, deals with 8,000 H.P. exclusively used for driving dynamos or alternators, the choice of the system of distribution having not yet been decided upon. Several schemes have already been brought up, amongst those one on the five-wire system, adapted for the supply of the motive power to the numerous tramways of the town at 500 volts pressure, and another one with alternators and double transformation. The Saleve Electric Railway is approaching completion, and will probably be open to the public in about two months' time.—Yours, &c., LOUIS GOICHOL.

Cie. de l'Industrie Électrique, Geneva, July 8, 1892.

MR. JACOB BRETT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The Council of the Institution recently brought to the notice of the First Lord of the Treasury the strong claims which, in their opinion, Mr. Jacob Brett has on the Government for some further pecuniary aid in his old age; and I am very happy in being able to inform you that their representation has resulted in a grant of £200 having been made to him from the "Queen's Bounty" on the recommendation of Mr. Balfour.

As you will probably be glad to notice this matter in your Journal, I venture to remind you that, in Part 95 of the Proceedings of the Institution, pp. 510-515,* you will find an admirable account by Mr. Latimer Clark of the important part taken by Mr. Brett and his brother, Mr. J. W. Brett, in the introduction of telegraphy, both land and submarine. In fact, to those gentlemen seems undoubtedly to belong the distinction of being the real pioneers of oceanic telegraphy.

It is a somewhat curious and in some sense a melancholy coincidence that this second mark of recognition by the British Government of Mr. Brett's services should have been conferred upon him within a few days of the lamented death of Mr. Cyrus Field, to whose indomitable energy the practical realisation of the Messrs. Brett's scheme for the establishment of an Atlantic telegraph was undoubtedly greatly due.—Yours, &c., F. H. WEBB, Secretary.

The Institution of Electrical Engineers,
London, July 19, 1892.

[* This account was also published in *The Electrician*, Vol. XXVIII., p. 64.—ED. *E.*]

THE DIMENSIONS OF PHYSICAL QUANTITIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I infer from your Note that in the endeavour to sum up concisely I have failed quite to convey my meaning. Prof. Rücker and Mr. Williams treat certain coefficients as concrete quantities. This they call taking account of the "suppressed dimensions" of μ and k. My contention is that the symbols of dimensional formulæ are numerical, not concrete quantities; and in the sentence "we prefer to suppress them all" I only meant to express that contention in Prof. Rücker's phraseology, not to suggest that the dimensional formulæ should be abandoned as useless. The more we use symbols as "thinking machines," the more need that the symbols and operations should be carefully defined, otherwise their "thoughts" are apt to be illogical.

I open my letter again to enclose an extract from the preface to a well-known treatise on Natural Philosophy, which seems to confirm the "disputable opinion" on which you comment:—

"We believe that the mathematical reader will especially profit by a perusal of the large-type portion of this volume, as he will thus be forced to think out for himself what he has been too often accustomed to reach by a mere mechanical

[* An abstract of this Paper will be found on page 303 of the present issue.—ED. *E.*]

Digitized by Google

application of analysis. Nothing can be more fatal to progress than a too confident reliance upon mathematical symbols; for the student is only too apt to take the easier course, and consider the *formula* and not the *fact* as the physical reality."—Yours, &c., W. M. M.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In "W. M. M.'s" interesting article on Mr. Williams' Paper on the "Dimensions of Physical Quantities," there occurs the following statement: "What we get out [of the electrical and magnetic dimensional formulæ] changes every day, but at present it includes that *electricity is ether*. . . ." Is it the case that any such deduction can be drawn from the study of these formulæ? In common with, I think, many other students whose mathematical equipment does not allow of their examining such questions very closely for themselves, I have understood that mathematical reasoning no more justifies using electricity than light as a synonym for the ether. If I am wrong I should be very glad to be corrected.—Yours, &c., E. M. C.

THE GREATHEAD SYSTEM OF TUNNELLING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to my Paper on Electric Traction, read before the Tramways Institute of Great Britain and Ireland on the 28th ult., and published in your issue of July 1st, my attention has been drawn by Mr. Greathead, M.I.C.E., to the statement that the "system of tunnelling is somewhat novel, and was introduced into this country by Mr. Greathead," is an error. Under date of 12th inst. Mr. Greathead writes me as follows:—"You are in error in supposing that the system of tunnelling with a tubular shield was first suggested in America. Beach's American patent was taken out when the Tower Subway (begun in 1868) was more than half driven under the Thames, and long after the shield used in that work had been described and illustrated in English journals (facts which must have been well known to the editor of the *Scientific American*)."

Kindly insert this letter in your next issue, and oblige, yours, &c., G. A. GRINDLE.

P.S.—I may add that the statement in my Paper above referred to was taken from the records of the Patent Office.

7, and 8, Great Winchester-street, E.C.,
July 14, 1892.

TRADE NOTES AND NOTICES.

Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.

TENDERS INVITED.—The Secretary of the Kildare-street Club, Dublin, is open to receive communications from firms wishing to be invited to tender for the installation of the mains and some of the fittings required for the electric lighting of the club. These communications must reach the Secretary on or before Thursday, the 28th instant (noon). Other particulars will be found in our advertising columns.

——— The Hull Corporation are prepared to receive tenders for wiring the Town Hall for electric lighting. Further particulars are given in our advertisement pages, and all other details may be obtained at the Borough Engineer's office, Town Hall, Hull. Tenders have to be in before 10 a.m. on Friday, August 5th.

——— The Gas Committee of the Leicester Corporation will receive and consider schemes, together with tenders, plans, and specifications, for the supply of electricity to their "limited area" in the centre of the town. Plans of the town and of the area to be lighted and all other particulars can be obtained from the Corporation's Engineer, Mr. Alfred Colson, M.I.C.E., at the Gas Offices, Millstone-lane, Leicester. Further particulars will be found in our advertising columns. Plans, &c., are to be in by Thursday, the 8th September next.

——— The Uxbridge Local Board invite tenders for the providing and fixing of an electrical tell-tale with electrical appliances and underground wire between their waterworks and reservoir, about 1¼ mile apart, to indicate at all times the depth of water in the reservoir. Particulars may be obtained of the Surveyor, to whom tenders are to be sent by the 31st inst.

APPOINTMENT VACANT.—The Commissioners of Hove require a competent electrical engineer to supervise the laying of their electric light mains and erection of plant, &c. Further particulars are given in our advertising columns.

FOR SALE.—Messrs. Wheatley Kirk, Price and Goulty have for sale (a bargain) newly-erected engineering works, with old-established connections, siding to main line, at the present time making fair profits. Further particulars are given in our advertising columns.

SALES BY AUCTION.—Messrs. Percy Matthews and Matthews announce the sale on Thursday, July 28th, at 17, Princes-street, Hanover-square (one o'clock) of the electrical plant, stock-in-trade and fittings of an electrical engineer, comprising a variety of lamps, holders, plugs, switches, &c., &c. Further particulars are given in our advertisement columns.

——— Messrs. H. N. Newton and Co. offer for sale on Monday next, July 25th, the valuable plant and machinery of a chemical electrician, on the premises, 85, Arlington-street, New North-road, London, N. Further particulars are given in our advertisement columns.

PERSONAL.—Mr. A. Calder has been appointed the National Telephone Company's London manager, in place of Mr. Dane Sinclair, who is now engineer-in-chief of the Company.

——— Mr. G. H. Nisbett and Mr. F. H. Jackson have been appointed second and third engineers respectively to the City of London Electric Lighting Company (Limited). Mr. Nisbett was formerly with Messrs. Paterson and Cooper; and Mr. Jackson with Messrs. Willans and Robinson (Limited), and were both, until recently, members of the staff of Major-General Webber.

MESSRS. GEORGE NORTH AND CO.—This firm have been appointed London representatives of Messrs. H. E. Hodgson and Co., of Cleckheaton, near Leeds, manufacturers of engineers' machine tools, &c.

EQUITABLE TELEPHONE ASSOCIATION (LIMITED).—A meeting of the shareholders in this Association (in voluntary liquidation) will be held at the office of Mr. C. L. Nichol, 1, Queen Victoria-street, E.C., on August 15th, at 12 o'clock, to receive an account of the winding up.

ALLCHIN, LINNELL AND CO. (LIMITED).—Proofs of debts in this liquidation must reach the liquidator, Mr. C. J. Stewart, 33, Carey-street, W.C., by August 15th.

FROUDE-HURRELL TORPEDO COMPANY (LIMITED).—This Company was on Friday, the 8th inst., ordered to be wound up, on the petition of Mr. Hurrell, a creditor.

MESSRS. DRAKE AND GORHAM.—Amongst the contracts recently obtained by this firm for the installation of the electric light, &c., are those for the London Assurance Corporation, Royal Exchange, E.C.; the Bank of Egypt, Old Broad-street, E.C.; and the Law Union Fire Office, Chancery-lane, W.C.

MESSRS. EVANS, STEWART, PALMER AND CO.—Amongst the recent installations effected by this firm is one at Messrs. Herring and Lake's, Great Portland-street, W.

MESSRS. E. J. DUGDILL AND CO.—This firm have just secured the contract for lighting the large entrance hall and new extensions at the City Art Gallery, Manchester.

MESSRS. RICHARD CRITTALL AND CO.—This firm have recently, under the personal direction of Mr. J. A. Phillips, their electrician, installed the electric light at the offices of the *Local Government Journal*, London. The current is supplied from the Salisbury Hotel installation, there being altogether about 600 incandescent lamps; Elwell-Parker dynamos, driven by two Marshall's 20 H.P. compound stationary engines, being used. Over 100 storage cells have also been provided.

HOVE ELECTRIC LIGHT COMPANY.—The Electric Light Committee of the Hove Commissioners have recommended that, as soon as certain preliminaries have been carried out, the seal of the Board should be affixed to the deed of transfer of the Provisional Order, &c., to the Hove Electric Light Company.

WHITEHAVEN.—Dr. Hopkinson, F.R.S., has just sent in his report on the electric lighting of Whitehaven to the Trustee Board. Dr. Hopkinson, in this report, calculates that electricity can be supplied at Whitehaven at less than 5½d. per unit, which is the comparative price of gas, which in Whitehaven is reported to be of inferior quality. The estimated outlay is £12,430, and the annual charges for maintenance and working £1,947. 10s., from which the probable receipts are estimated to amount to £2,606. The report is an interesting one, and appears in full in the *Cumberland Pacquet* of the 14th instant.

ST. HELENS.—A trial of the new electric lighting arrangements at the Town Hall and municipal offices took place on Monday last, July 18th. The installation consists of 338 lamps. The whole of the plant has been supplied by Messrs. Bumsted and Chandler, and the wiring arrangements have been carried out by Messrs. J. D. F. Andrews and Co. The total outlay has been about

Digitized by Google

£1,500, and it is estimated that the cost will be less than that of the gas, and that a distinct saving will result to the ratepayers.

ABERDEEN.—The Gas Committee of the Aberdeen Town Council have recently purchased for £1,900 the large building known as the Bon Accord Mills, with the intention of utilising it in connection with the supply of electric light to the city when the Corporation take that subject in hand.

YARMOUTH.—At the last weekly meeting of the Town Council the Electric Lighting Committee presented their report containing the conditions and instructions for fitting up the electric lighting installation. A tender was read from Messrs. Crossley Brothers offering to instal the electric light on the Marine Parade for £250 per annum. After some discussion, however, the Council decided not to entertain the matter for the present; it being finally agreed to consult Mr. W. H. Preece in the matter.

SOUTHAMPTON.—At the last meeting of the Town Council it was notified that the Local Government Board would hold the usual inquiry in respect to the application of the Council to borrow £650 for electric lighting purposes.

GRIMSBY.—At the last meeting of the Town Council the question of the electric lighting of the Town Hall was discussed, and the Chairman remarked that the cost of the electric light compared with gas showed a distinct saving.

ELECTRIC LIGHT FOR RAILWAY STATIONS.—The Caledonian Railway Company have been granted permission by the Edinburgh Dean of Guild Court to erect electric light appliances at their Princes-street Station.

HANLEY.—At a meeting of the Town Council on Tuesday the General Purposes Committee recommended that the Borough Surveyor be requested to prepare a report on those tenders for electric lighting which utilised a site on the canal side for the central generating station, and that the Borough Surveyor obtain from the different firms tendering for the street arc lighting such explanations and prices as would enable them to be placed on an equal footing.

HECKMONDWIKE.—An electric lighting scheme has been prepared under the direction of Mr. Hutchinson, C.E. It is to be an overhead system, with both arc and incandescent lights. The scheme embodies three sets of compound engines and dynamos, of which two sets only are required for an output of 1,000 lights, one set being kept in reserve, and two boilers are provided. The estimate of the cost shows the initial outlay to reach about £4,450, whilst interest, depreciation, and maintenance are put down at £1,048 per year. The estimated annual revenue is £1,432.

HOTEL LIGHTING.—The new Royal Palace Hotel, at Kensington Gardens, which is in course of construction by Messrs. Perry and Co., at an estimated cost of about £200,000, will be lighted throughout by electricity. It is expected that the hotel will be opened about February or March next.

LAUNCESTON (TASMANIA).—The City Council of Launceston have adopted a report favouring the lighting of the city with the electric light.

NEW JOURNAL.—Under the title of *Transport* a new journal has been started, dealing with docks and harbours, canals and railways.

EXHIBITION.—There is to be a Distillers', Brewers', Mineral Water Trades' and Appliances Exhibition at the Rotunda, Dublin, from August 15th to 27th. Firms desirous of exhibiting are invited to apply to the Secretary, at 69, Lower Gardiner-street, Dublin.

KING, MENDHAM AND CO.—On Saturday last the employés of this firm had their annual outing at Plymouth. Between 50 and 60 sat down to dinner. The firm defrayed all the expenses of the excursion.

STAMP DISTRIBUTION.—It will be remembered that some time ago a syndicate was formed for the purpose of floating an invention for the automatic distribution of stamps in connection with street pillar-boxes. Yesterday (Thursday) a gathering of press-men, and of gentlemen interested in the question, took place at the Cannon-street Hotel, E.C., and the latest form of the automatic stamp distributor was shown. It is intended to float a company to place this machine upon the market, and it is claimed that so self-evident a public convenience must have considerable success; certainly those present were satisfied of the capabilities of the machine to perform the functions for which it is intended, and it now seems only essential to success to obtain the full approval of the Postmaster-General. It may be that this approval has been already obtained, but no indication was given at the meeting that this was the case.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1892.—The tenth annual edition of the above well-known annual is on sale, price 7s. 6d.; post free, in the United Kingdom, 8s. 3d.; abroad (a few countries excepted), post free, 8s. 10d. A digest of the contents will be sent on application.

BOOKS, &c., RECEIVED.

"School of Mines Quarterly." April, 1892. (New York: Columbia College.)

"Notes on Design of Small Dynamos." By George Halliday, Whit. Sch. (London: E. and F. N. Spon.)

"Das Räumliche Wirken und Wesen der Elektrizität und des Magnetismus." By Prof. Max Möller. (Hanover-Linden: Manz and Lange.)

"Telephones, their Construction and Fitting." By F. C. Allsop. Second edition. (London and New York: E. and F. N. Spon.)

COMPANIES' MEETINGS & REPORTS.

African Direct Telegraph Company (Limited).

The following is the report of the Directors, to be submitted to the ordinary general meeting, to be held at Winchester House, Old Broad-street, E.C., to-day (Friday), the 22nd inst., at 11:30 a.m.:—

The income for the year ended December 31, 1891, amounted to £53,021. 11s. 11d., consisting of £33,444. 6s. 4d. from traffic, £19,000 from subsidy, £577. 5s. 7d. from bank interest, rents and transfer fees. The working expenses, interest on debentures, sinking fund, and income-tax amounted to £41,281. 19s. 7d., leaving a balance of £11,739. 12s. 4d.; to this is added £1,023. 0s. 6d., brought forward from December 31, 1890, making a total of £12,762. 12s. 10d. A dividend of 4s. per share, amounting to £4,720, has been paid in respect of the half year to June 30th, leaving the sum of £8,042. 12s. 10d. to be dealt with Of this the sum of £3,000 has been transferred to the reserve fund; and the Directors now recommend the declaration of a dividend of 4s. per share to December 31, 1891, which will amount to £4,720, leaving a balance of £322. 12s. 10d. to be carried forward.

In accordance with the provisions for the repayment of the debentures, 549 bonds, representing £54,900, were drawn on May 5th last for payment at par on July 1st instant.

The Accra-Lagos cable referred to in the last report as having been interrupted on July 2, 1891, was successfully repaired by the Eastern Telegraph Company's s.s. "Amber," on August 1st following. The cause of the break is believed to have been due to suspension and a slight subsidence of the bank upon which the cable was laid. On October 5, 1891, a fault appeared in the Lagos-Brass cable, and was subsequently removed by the s.s. "Mirror," belonging to the Eastern Telegraph Company.

In accordance with the provisions of the Articles of Association, two of the Directors, Sir James Anderson and the Hon. W. St. John F. Brodrick, M.P., retire by rotation, but offer themselves for re-election. The Auditors, Messrs. Deloitte, Dever, Griffiths and Co., also offer themselves for re-election.

United River Plate Telephone Company (Limited).

The following is the report of the Directors, to be presented to the shareholders at the ordinary general meeting, to be held at Winchester House, 50, Old Broad-street, E.C., on Tuesday next, the 26th inst., at 3 o'clock:—

After payment of all expenses in the River Plate, debenture interest and all London charges, the profit at par of exchange is £30,069. 7s. 11d. on the Company's operations during the year ended March 31st, to which has to be added the sum of £2,037. 2s. 6d., brought forward from last year, making a total of £32,106. 10s. 5d.; from this has to be deducted the loss on exchange of £31,741. 0s. 8d., leaving a balance of £365. 9s. 9d., to be carried forward to the credit of profit and loss account for the current year. As shown in the balance-sheet, the capital expenditure during the year amounted to £1,008. 18s., as against £3,096. 10s. 10d., in the previous twelve months, and £12,772. 8s. for 1889-1890. The loss on exchange, £31,741. 0s. 8d., represents nearly 11 per cent. on the Company's paid-up share capital. The working expenses in the River Plate amounted at par of exchange to £58,618. 9s. 8d., against £56,941. 1s. 9d. during the previous year; this increase is mainly due to the augmented cost of materials, cartage, gas, and other expenses, owing to the depreciation of the paper currency. The London expenses were £1,638. 2s. 5d., against £2,732. 14s. 9d. for 1890-1891.

The Directors are glad to state that, since March 31st last, the business of the Company has improved in sympathy with the better condition of affairs in the Argentine Republic; it is expected, therefore, that the working for the current year will be much more satisfactory than for the year now under review.

Under the Articles of Association, Mr. George Cooper and Mr. Alfred Le Rossignol retire by rotation, and, being eligible, offer themselves for re-election. The auditors, Messrs. Cooper Brothers and Co., also retire, and offer themselves for re-election.

Edison and Swan United Electric Light Company (Limited).

The annual meeting of the shareholders of this Company was held on Tuesday, at the City Terminus Hotel, Cannon-street, under the presidency of Mr. James Staats Forbes.

The SECRETARY (Mr. H. Charles Gover) having read the notice calling the meeting, the Directors' report was taken as read.

The CHAIRMAN said: I have had occasion before to call attention to the conditions of a Company like this, where circumstances operating in its interests make it expedient that the accounts should be stated in a manner rather more general than in some other companies which have a statutory form of account. I suppose, as the period arrives when our patents are running out, that reticence becomes even more necessary than in our earlier stages, and that is why these accounts are so brief in statement, and are confined to so few elements as compared with the accounts of some other public companies. Of course, the essence of all these reports is what profit has been made and how do we propose to divide it. I want to remind you of the peculiar position of this Company, and why, however satisfactory the result as shown upon a particular year may be in the distribution of dividend, it is necessary to bear in mind that there are some considerations acting rather in depreciation of that dividend. For instance, we shall to-day propose to divide such an amount of the profit realised in the year as with the provisional dividend paid six months ago will amount to 18 per cent. Last year we paid 17 per cent., the year before we paid 15 per cent., and in 1889—our first dividend paying year—we paid 10 per cent. Nothing is so readily excited as the cupidity of mankind; and as our business is being watched by a great many outsiders who, when it becomes an open business, will be ready to launch upon it in competition with us, it is just as well to bear in mind that for the five preceding years of our existence—the years prior to those which I have referred to—we paid no dividend at all; and perhaps it may qualify, not our satisfaction, but the aspirations of some other people to know that, notwithstanding we propose to pay this dividend to-day, really over the whole nine years of our existence the aggregate amount divided by us has only reached the moderate return of 6½ per cent. It is just as well that that should go forth to the outside world, because we know that there is a disposition on the part of the public themselves—the consumers—to think themselves aggrieved when the Company who manufactures what is consumed appears to be paying a considerable dividend. There is also the other influence—the cupidity excited to enter into the competition upon the theory that it must be a gold mine. Now, as to the accounts themselves. I had better take you through what is called the profit and loss, or the working account. It is very simple, and consists of only three or four heads. We begin every year, of course, with a large stock of lamps and material in anticipation of the requirements of the current year. The amount of that stock carried forward from year to year is a matter of some importance in forming an opinion as to the position of the Company. It may be too large or too small. If it is too small the Company may be placed at a disadvantage in the event of there being a sudden call for lamps—a sudden growth in the demands for them; or it may be too large, and involve the locking up of more than the necessary capital invested in the stock. Well, on July 1, 1891, we brought into the account stock of the value of £59,308. That is made up largely of lamps and of platinum, and other materials in hand. During the year, to keep abreast of the consumption, notwithstanding the possession of a large stock, we have spent in wages, purchases of material, &c., £59,001. That is the bare cost of the lamps, &c., produced at the factory—the mere mechanical part of producing the material and working it up into the production of so many lamps. Then come the whole of the administration expenses—the various heads of departments, the Directors, and all that machinery representing in a public company what the brains and directing influence of a partner or partners represent in an ordinary firm. A small amount is put down for depreciation of plant, &c., which, according to our judgment, is sufficient. On the other side of the account it is stated that the sale of lamps, &c., has produced £166,349; interest is put down at £473, and the stock on hand when we emerged from last year amounted to £45,225. Of course the difference between those two aggregate amounts is the balance of profit to be dealt with for the year, and that amounts to the respectable sum of £74,810. Now, what I want rather to call attention to is that this account is satisfactory in the sense of having diminished, and considerably diminished, the amount of money which is locked up in stock; and I think I may say that that is so without at all fearing the question upon the other possibility—that there is not stock enough on hand to meet any sudden emergency. I think we may say that to that extent our position is a little more wholesome than it was this time 12 months ago. We have produced that state of things by dealing fairly liberally with the elimination from the accounts of stock which had become more or less effete; in fact, we have written it down. Some considerable portion of it has gone to make up the increased income derived from sales, but a not inconsiderable portion of the difference has gone to writing down the value of the stock on hand carried forward into the account this year. I think you will consider that that is a safe and prudent thing to do. With reference to the sales, the large sum of £166,349 is not made up exclusively of the sale of lamps, because for the last two or three years we have been manufacturing fittings which are an adjunct to the lamps. Lamps are very delicate and wonderful instruments, but they require to be fitted in a variety of ways, according to the taste and ideas of the consumers; and we were driven to manufacture fittings, first of all because the holder of the lamp, which has become by the process of invention a part of it, was a very delicate operation, upon which a good deal of the convenience and use of the lamp depends, and we found we could do it better than anyone else. We therefore secured certain patents for fittings, and we are manufacturers and licensors. We have also a great many respectable firms in this trade—people who were gasfitters have become also electric light fitters, and we found it convenient to give them the opportunity of manufacturing fittings themselves if they chose. They do this on the theory of a royalty; and from the profit on the fittings we manufacture, and the royalties paid by these licensees, we receive a considerable annual sum, the advantage being that whereas the lamp patent will expire at no very remote date, the patents for these fittings and inventions run on for many years, and will afford us during what may be called "the protected period" a very considerable and growing annual profit. As to the balance of £74,810, we have already distributed in the course of the year a considerable portion of that in the nature of a dividend, and we propose to apportion the remainder of it so as to produce this 18 per cent. for the year. In order that you may understand that, I must refer you to paragraph 2 of the report, which is somewhat long-winded, and is somewhat complicated. It only repeats, however, what I have already told you—that the dividend of the particular year being limited to 7 per cent., all the rest of the profit goes in aid of those years during which no dividend was paid, because the 7 per cent., according to the contract between the partners, was to be cumulative. In addition to the capital on which this is divided, we have £117,000 of Deferred shares, representing Mr. Edison and his friends' proportion of the capital in this business—the consideration, in fact, for his patents and so forth. He has never received anything at present, nor can he or those who hold these shares receive anything until the shareholders of the Company—the A shareholders—have received 7 per cent. not only in respect of the current year, but in respect to all past years; and now, as you see by paragraph 2 of the report, we have wiped out everything up to the 30th June, 1888. We still have on that account a considerable sum to meet out of the profits of future years before the Deferred shareholders get anything. The appropriation of the balance of £74,810 is shown in the statement below the balance sheet. You see from that statement the profit brought down from the working account which I have just mentioned. The dividend for the year ended the 30th ult., at 7 per cent. per annum, is £24,743; the payment of cumulative preferential dividend on the A shares for the year ended June 30th, 1887, at 7 per cent. per annum, is also £24,743; and then there is for payment on account of this cumulative dividend on the A shares for the year to June 30th, 1888, at the rate of 4 per cent., £14,139. Those three sums amount to £63,626, which is the amount we propose to distribute out of the £74,810, and the balance we propose to carry to the reserve fund. That, of course, requires your confirmation, and we shall submit to you a resolution authorising that application of the balance, if you approve it. With regard to the statements in the report, the Directors are glad to say that the electrical fittings business is prospering. The amount received as royalty from those who hold licences for manufacturing holders and sockets for incandescent lamps is satisfactory, and is likely to increase year by year. I have told you in other words the same story as to why we entered on the manufacture of these fittings, &c. This is a growing asset and one giving us great advantage, being protected, as it is, for a good many years. I now come to paragraph 5, which in very brief words records what in the earlier days of the Company would have been a positive calamity to us; and even in these days, when we have got this thing upon something like a sound basis, is a very great loss to us—I refer to the death, the very sudden death—it was almost awful in its suddenness—of Mr. Leyland. If I were to say what I feel personally about this I should say a good deal. If I attempted to enlarge upon how great his services were to this Company, how much our issue from tribulation turned upon his judgment and courage, I should also have to say a great deal; but it has been said so often that I am sure it must be familiar to the proprietors. I will, therefore, not enlarge upon it except to express our regret and the sense of loss we feel at the death of so able a colleague. I am quite sure that the shareholders who have been accustomed to hear and see him, and know what he was, will share very deeply with us in that feeling. His death created a vacancy, which had to be filled, and we thought, looking to the position which Major Flood Page had held in the concern for a good many years, that, like some others among us, he was not getting younger, and that the time had come when he might very properly be relieved of some of the harassing duties of a business which is made up of innumerable details, constantly changing in its elements, growing in its scattered relations all over the kingdom, and with a large factory involving enormous manipulation to support. We therefore thought we might put him on the Board in place of Mr. Leyland. I need not say that either the chairman or the deputy-chairman of a public company has rather more work cast upon him in the way of attendance than the Directors generally. Boards are, of course, composed of several gentlemen who meet at stated intervals, and frequently if need be, but very few Boards are so constituted that the gentlemen composing them can go to the business very often, or, if necessary, every day of the week. Therefore the chairman and the deputy-chairman have to take upon themselves not only the ordinary duties of Directors, but also the general business, and they have to devote a good many hours of every week, and sometimes every day, to watching the details of a business of this sort. I hope you will confirm the judgment of the step which we took in this matter. The Earl of Lichfield and Mr. Ernest Villiers retire by rotation from the Board, and being eligible they offer themselves for re-election; and the auditors also retire. That really is pretty nearly all that I have to say on the report. The balance-sheet, I think, you can probably judge

Digitized by Google

of for yourselves. As regards the capital account, things are left where they were. It shows the different items that go to make up the capital The capital is about £353,000, and then you have 23,564 B shares, representing £117,000. They are the shareholders who get nothing until you have had your 7 per cent. cumulative. Then there are sundry credit balances which we owe, amounting to £16,493: but that may set against debtors on the other side, amounting to £30,809. We are, therefore, all right there; and our debtors are all good. On the credit side of the balance-sheet you see where the money of the shareholders has gone to. The sum of £236,000 represents the cost of the patents, goodwill, preliminary outlay, loss on working, &c. In the Manchester Edison-Swan Company we have £12,000 upon which no dividend is paid to us at present. I do not know whether it is within the bounds of possibility that that Company may so develop in time as to be able to pay a dividend on their Deferred shares. If they do, that asset will be worth something; if not it will not be worth much. In freehold property we have £39,453, and plant and stock stand for £67,000. With respect to our freehold property we have bought a considerable acreage of land at Ponder's End, with enormous buildings upon it, for the purposes of a factory; and that land and property was sold to us at a time of great depression and under circumstances which made the bargain for us exceedingly advantageous. The plant and stock represent the two items I have mentioned of lamps, &c., in hand, and the plant and machinery which we, out of capital, paid to make that factory a going concern. I suppose I may sum up this matter by saying that if we had to start afresh and find land in a position as advantageous, and had to put on it buildings and plant as efficient as we have there now, it would cost a great deal more than these two sums represent, from which I draw the inference that as long as this business can be proceeded with, we have a factory and land bought very economically, and as its capacity for production is very large, for a good many years as a going concern it will be of great value to the Company, and may be regarded as a very sound asset. We have investments in Consols at cost, figuring for £20,000; and cash at bankers and in hand amounting to £30,719. That is the state of the accounts, and, as I said before, it is very simple. Subject to being ready to answer any questions, I will now propose—

"*That the report and accounts for the year ending June 30, 1892, be received and adopted.*"

The DEPUTY CHAIRMAN (Major Samuel Flood Page) seconded the motion.

Mr. LORRAIN said that with reference to the question of the expiration of the patents, and the competition which that event might produce, if there were 100 competitors they would simply advertise this Company's goods. One argument was that foreign lamps would be introduced, made where labour was very cheap. Upon that point he would like to ask Mr. Forbes whether his (the speaker's) view was correct—that whatever occurred in that way their Company would have no loss; for, as he understood, the Swan Company had factories where labour was very cheap. Was he right that the Edison and Swan Company and the Swan United Company worked so hand in hand that when the time in question came, they would be able to gain by one hand what they lost by the other?

The CHAIRMAN: This is an exceedingly interesting question, and, as the honourable proprietor observed, does bear so very much upon the figures that I can only congratulate my colleagues and myself upon having stated so clearly to you what has guided us very much in our policy over a good many years. As you know, we went through some difficulties and troubles. We had to eliminate from the business the errors of its youth—the installations which did not pay, the contracts to light, upon which there was a severe loss. We had, in fact, the courage to pull ourselves together, and cut the first loss, and to confine ourselves to the comparative humble *rôle* of making lamps; and for a great many years we have avoided the risks of installations, leaving that work to the electric lighting companies, and confining ourselves to the lamps. As an illustration of having at one's elbow a man of courage—in fact, two men—I may mention that when our litigation was carried to a decision in the Law Courts, we found our patents protected; but we found a strong disposition on the part of very high legal authorities to advise that, instead of retaining the manufacture exclusively in our own hands, we should give it out to licensees. Now, although we had the highest respect for the legal abilities of the distinguished men who gave that advice, we made up our minds that we would not follow it. We thought that if we retained the exclusive control of the manufacture, we should do two things—probably attract to ourselves such inventions as there might be during the protected period, and that we should certainly have the opportunity of insisting on the most efficient production of the lamps. We should thus build up in the market a reputation for the best article, and establish for ourselves a *clientèle*, so that when we emerged from the protected period into the competition we should have the advantages of a good name, a good article, and a large connection. I believe that was very wise, and I believe it will tell, because I quite agree with Mr. Lorrain that patents have their advantages, but they also have their disadvantages. I wonder if I can go so far as to suppose it possible that if there had been no patent in these lamps, the sale of them might have been rather larger. I think that rather likely under free competition, especially as the circumstance, happily for us, of what I may call the expansion of electric lighting has gone on through the means of the electric light companies, who are popularising the lamp. I think, however, we shall find that, although we have had certain advantages of price and exclusive dealings during the term of the patent, when we are in the open market there will be such a gradual developing to such a large expansion of this business that the profit will really remain in the hands of those who have the best trade mark and the best hold upon the business. Now, that is what we felt, and that is what Mr. Lorrain has put before you. I do not, therefore, think that we need suppose that a large return upon the capital of this Company is going to be knocked suddenly out of existence.

The resolution was then submitted to the meeting and carried unanimously.

The CHAIRMAN afterwards proposed the following resolution:—

"*That a dividend be, and is hereby, declared on the "A" shares of the Company of* 5*s.* 8½*d. per share on the* 89,261 *ordinary shares,* £3 *paid; of* 9*s.* 6½*d. per share on the* 5,000 £5 *fully-paid shares allotted to the Edison Electric Light Company (Limited); and of* 8*s.* 10½*d. per share on the* 12,139 £5 *fully-paid shares allotted to the Swan United Electric Light Company (Limited), free of income tax, being, with the interim dividend paid on February* 22, 1892, 7 *per cent. in respect of the year ending June* 30, 1892; 7 *per cent. in payment of arrears of cumulative preferential dividend for the year ending June* 30, 1887; *and of* 4 *per cent. in respect of the year ending June* 30, 1888; *all to be distributed in accordance with the provisions of clause* 87 *of the Articles of Association, and that the balance be carried to reserve.*"

The DEPUTY CHAIRMAN seconded the motion, which was carried unanimously.

Resolutions were afterwards passed, re-electing the retiring Directors (the Earl of Lichfield and Mr. Ernest Villiers), and the auditors, Messrs. Welton, Jones, and Company.

A vote of thanks to the Chairman and Directors was unanimously agreed to, which was acknowledged; and the proceedings terminated.

Manchester Edison-Swan Company (Limited).

The annual meeting of this Company was held on Monday, at the Victoria Hotel, Manchester; Mr. V. K. Armitage, Chairman of the Company, presiding.

The Directors' annual report stated that the net profits for the year, including last year's balance, amounted to £2,826. 1s. 10d. Out of this it was proposed to pay a dividend at the rate of 5 per cent. per annum, which will absorb £1,000, to carry £1,000 to reserve fund, and to carry forward a balance of £826. 1s. 10d.

On the motion of the CHAIRMAN, seconded by Mr. W. P. JAMES FAWCUS, the report was adopted, and the dividend recommended therein was declared payable. Mr. Armitage was re-elected a Director of the Company, and votes of thanks were accorded to the Directors for their services.

Electrical Power Storage Company (Limited).

The third ordinary general meeting of this Company was held at 4, Great Winchester-street, E.C., on Wednesday, the 20th inst. Mr. John Irving Courtenay presided.

Mr. J. W. BARNARD (the Secretary) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN said: Gentlemen, I intend to make but few observations to-day. The Directors' report and balance sheet I know you will regard as very satisfactory. The dividend of 6 per cent. has been earned by our secondary battery manufacturing business at Millwall during the twelve months that have elapsed since we took it over from the Electric Construction Corporation, and it is for that period; you will be pleased to learn that a most gratifying increase of business has taken place in that time. The financial position of the Company is a strong one—a good balance of cash, nearly £10,000, at our bankers—and current accounts due to us upwards of £11,000, as against about half that sum owing by the Company, and there is still a substantial amount of uncalled capital. I must here heartily thank our manager (Mr. Frank King) and our staff for the skill and energy he and they have displayed during the past year. The E.P.S. batteries continue to hold the field against all comers. The award of the only gold medal given solely for secondary batteries at the Electrical Exhibition at the Crystal Palace is a fresh proof of the unrivalled excellence of the E.P.S. batteries. Numerous secondary batteries continue to be introduced so far as Blue Books, specifications, laboratory experiments, and newspaper paragraphs can introduce them; but they all die shortly after their birth, and in a commercial point of view are heard of no more. During the last ten years, scarcely a year has passed without some alleged improvement having been trumpeted forth as about to revolutionise the storage battery business; but the supporters of these inventions are now sadder, if not wiser, men.

Because we make the best battery in the market we do not therefore say "rest and be thankful:" on the contrary, Mr. King is always on the *qui vive* to improve, if possible, the E.P.S. manufactures, and to keep the foremost position, of which you have tangible proof in the largely increased sales of the E.P.S. batteries for lighting and other purposes.

For traction purposes especially we may look for an increased demand for the E.P.S. batteries, and close attention is being given to this particular branch of the business. I think there should now be a further improvement and further development in our foreign business, which has been hindered by competitors in several directions; but the Courts in various countries are, I think, at last arriving at conclusions favourable to the interests of those who are supporting the patents, as for instance the decision of the Imperial Court of Appeal at Leipsic, by which the validity of the Faure patent in Germany is finally decided; and again, the decision in favour of the Swan patent recently given in the United States. In this connection I may add that the Directors are also keeping a watchful eye upon what is being done by others in the storage battery business in this country, and it may yet be their duty to take steps for the more effectual protection of our British business. I do not propose to detain you longer, and will conclude by stating

Digitized by Google

that I consider the prospects of the Company are excellent. I beg to move the following resolution :—

"*That the Directors' report and statement of accounts to May 31, 1892, be and are hereby approved and adopted, and that a dividend of 6 per cent. on the paid-up capital be declared, payable on the 21st inst.*"

I will ask Sir Daniel Cooper to second the resolution.

Sir DANIEL COOPER, Bart., G.C.M.G.: Gentlemen, it is not necessary for me to extend at any length the observations of your Chairman, Mr. Courtenay, except upon one point, which I think is a very clear one. It is well known to you that the old E.P.S. Company was taken over by the E.C.C. Company, and the business of the Company after it went into their hands decreased, but within twelve months of the time of taking it over we have regained all that was lost, and we hope to do a larger business in the present year than we have done during last year. So far as we know, and can estimate, I may assure you that although our patents—the time for our patents —may shortly expire; yet under the system of making secondary batteries pursued at the present time, it is almost impossible—as far as I can see—at all events, at the present time, for anyone to make batteries of any better quality than we have been making and shall continue to make, and which we have sold from time to time. I have no doubt that the business will be maintained if we continue to manufacture goods of the quality that we have done, and I feel quite confident myself that this Company will continue to be very successful. I have, gentlemen, great confidence that the business will prosper, and that we shall earn for you a very good dividend.

The CHAIRMAN then invited discussion; and no questions being asked, he said: Since there is no opposition to it I will put the resolution. Those in favour—on the contrary. It is carried unanimously. Now, gentlemen, the second resolution which I have to propose is one for the re-election of two of our Directors, Mr. Frederick Green and Mr. James Pender. Mr. Frederick Green has been, as you all know, a Director of the Electrical Power Storage Company from the very beginning, but Mr. James Pender has only joined us since what I may call the new Electrical Power Storage Company came into existence. I have much pleasure in proposing the re-election of these two gentlemen. The resolution is as follows :—

"*That the retiring Directors, Mr. Frederick Green and Mr. James Pender, be and are hereby re-elected Directors of the Company.*"

Sir HENRY MANCE, C.I.E., seconded the motion, and the resolution was unanimously carried.

The CHAIRMAN: The next resolution must be moved by the shareholders—it is the re-election of auditors.

Sir HENRY MANCE: I shall have much pleasure in proposing—

"*That the auditors, Messrs. Broads, Paterson, and Co., be voted a fee of £120 for their audit of the accounts to May 31, 1892, and that they be and are hereby re-elected auditors of the Company for the ensuing year.*"

Mr. W. SAMSON seconded the motion, and the resolution was unanimously carried.

The CHAIRMAN: Thank you, gentlemen, for your attendance. This is all the business that we have got to do to-day, and I hope that upon future occasions we shall have an equally satisfactory and short meeting, and that the result will be equally good.

On the motion of Sir HENRY MANCE, seconded by Mr. GREEN, a vote of thanks was accorded to the Chairman for presiding; and the meeting separated.

Sheffield Telephone Exchange and Electric Light Company (Limited).

The third ordinary general meeting of this Company was held at the Cutlers' Hall, Sheffield, on Monday. The report of the Directors was adopted. The sum of £795. 6s. 11d. was added to the reserve fund, and a dividend at the rate of 5 per cent. per annum was declared upon the ordinary shares.

At an extraordinary meeting subsequently held it was decided to reconstruct the Company, under the title of "The Sheffield Electric Light and Power Company (Limited)," having for its object the exploitation and development of the Parliamentary powers recently granted to the Company for the electric lighting of a compulsory area in the centre of the town, and also the application of electricity to commercial requirements generally, respecting which there is a largely-increasing demand. The Directors propose to pay off all the preferential shareholders with interest to date, and to reduce, to some extent, the capital of the Company, this course being rendered possible by the sale of the Company's telephone exchange.

Direct United States Cable Company (Limited).

The following is the report of the Directors, to be presented at the ordinary general meeting of the Company, to be held at Winchester House, Old Broad street, E.C., on Friday next, the 29th inst., at 2 p.m.:—

The revenue for the half-year ended June 30, 1892, after deducting outpayments, amounted to £39,014. 14s. 1d., against £37,352. 19s. 5d. for the corresponding period of 1891, being a difference of £1,661. 14s. 8d. in favour of the half-year under review. The working and other expenses for the same period, including income-tax, but exclusive of cost of repairs of cables, amounted to £19,018. 11s. 3d., leaving a balance of £19,996. 2s. 10d. as the net profit of the half-year, making, with £4,982. 15s. 3d. brought forward from the previous half-year, a total of £24,978. 18s. 1d. For the corresponding period of 1891, the working expenses and other payments amounted to £18,112. 19s. 8d.

Three quarterly interim dividends of 3s. 6d. each per share, amounting to £31,872. 15s., have been declared and paid during the financial year, and a final payment of 3s. 6d. per share is now proposed, making, with the three interim dividends, 3½ per cent for the year, being a total distribution of £42,497. The balance of £3,730. 8s. 1d. on the revenue account it is proposed to carry forward.

During the period under review, repairs have had to be made in both sections of the Company's cables at a cost of £9,385. 6s. 2d., which has been debited to the reserve fund account as heretofore, the balance of which now stands at £254,716. 13s. 10d.

The Directors have to report with extreme regret the deaths of their esteemed colleagues, Mr. William Ford on May 14th, and Admiral R. C. Mayne on May 29th last. The vacancy on the Board occasioned by Mr. Ford's decease has been filled up by the election of Mr. James Pender. It is not intended at present to fill up the second vacancy. Pursuant to the provisions of the Articles of Association, two of the Directors, viz. :—C. J. Günther, Esq., and Admiral of the Fleet the Hon. Sir Henry Keppel, G.C.B, D.C.L., retire by rotation, and, being eligible, offer themselves for re-election. Mr. John G. Griffiths, F.C.A., and Mr. John Sawyer, F.C.A., the auditors, retire pursuant to the Articles of Association, and offer themselves for re-election.

Anglo-American Telegraph Company (Limited).

The following report has been issued by the Directors of this Company, and will be presented at the meeting of the proprietors, to be held on Friday next, the 29th inst., at Winchester House, E.C., at 2 o'clock :—

The total receipts from January 1st to June 30, 1892, including the balance of £864. 6s. brought forward from the last account, amounted to £147,818. 19s. 9d. This sum, however, is subject to revision, as the lawsuit between this Company and the Paris and New York Telegraph Company is still pending before the Court of Appeal in Paris.

The traffic receipts show an increase of £10,035 as compared with the corresponding period of last year.

The total expenses of the half-year, including the repair of cables, &c., as shown by the revenue account, amounted to £59,364. 1s. 10d.

One quarterly interim dividend of 12s. 6d. per cent. on the ordinary stock, and of £1. 5s. Cd. per cent. on the preferred stock, was paid on April 30, 1892, absorbing £43,750, and a second quarterly dividend at the same rates will be paid on July 30, 1892, leaving a balance of £954. 17s. 11d. to be carried forward to the next account.

The Company's repairing steamship "Minia" has been engaged during the past half-year in the repair and partial renewal of the 1869 cable between Brest and St. Pierre, Miquelon, at a distance of 270 miles from Brest, and also in the repair and diversion of the North and South Placentia cables, between Placentia and St. Pierre.

The Company's cables and the land lines in connection therewith are in good working order, with the exception of the Brest-St. Pierre cable, which was again broken on the 14th inst. The disastrous fire which occurred at St. John's, Newfoundland, on the 9th inst., destroyed the telegraph station and the local wires in the immediate vicinity; the instruments, however, were saved and transferred to temporary offices, from which they are now being worked. The telephone system belonging to the Company was also partially destroyed. This accident does not in any way affect the through communication on the Company's main Atlantic cables.

Little or no progress has been made since the last report in the lawsuit so long pending between this Company and the Paris and New York Telegraph Company.

The Directors greatly regret to announce the death of their highly valued colleague Mr. Cyrus W. Field, which occurred on the 12th instant.

Mr. Field was amongst the first believers in the possibility of connecting Europe with America by submarine cable, and by his untiring energy and ceaseless advocacy on both sides of the Atlantic largely contributed to the successful establishment of the first Atlantic telegraph cables.

Globe Telegraph and Trust Company (Limited).

The following is the report of the Directors of this Company, to be presented to the nineteenth ordinary general meeting to be held at Winchester House, E.C., on Tuesday, the 26th inst., at one o'clock :—

The net revenue for the year ending July 18th inst., after deduction of expenses, amounts to £192,243. 16s. 6d., and makes, with the balance of £1,876. 15s. 9d. brought forward, a total of £194,120, 12s. 3d. From this amount there has been distributed the sum of £133,059. 8s. 3d. in interim dividends, leaving an available balance of £61,061. 4s. The Directors recommend the payment of a final dividend for the year of 3s. per share on the preference shares, and of 3s. 9d. per share on the ordinary shares, making, with the former distributions, a total dividend for the year of 6 per cent., less income tax, upon the preference, and 4½ per cent. net (against 5½ per cent. for the preceding year) upon the ordinary shares, and carrying forward a balance of £938. 4s. 1d.

The Imperial German Government have, in virtue of their agreement entered into with the German-Norwegian Telegraph Company, taken over that Company's undertaking, and have paid off its capital. On reference to last year's report, it will be seen that 95 per cent. of this Company's investment in the German-Norwegian Company had been received in that year, the balance received in February of the present year has been invested in the West Coast of America Telegraph Company's Shares.

The Directors regret to report the death of their much-valued colleague, Mr. William Ford. Lord Sackville A. Cecil has been elected to fill the vacancy on the Board of Directors. The Directors have also to record, with much regret, the decease of Mr. W. Payton, who occupied the post of Secretary to this Company for many years.

In conformity with the Articles of Association, Sir John Pender, K.C.M.G., M.P., and Sir James Anderson, two of the Directors, retire,

Digitized by Google

and offer themselves for re-election. The auditors, Mr. John George Griffiths, F.C.A. (Messrs. Deloitte, Dever, Griffiths and Co.), and Mr. William Griffith, B.A., Barrister-at-Law, also retire at the meeting, and offer themselves for re-election.

Telephone Company of Austria (Limited).

The following is the Directors' report, to be presented at the ninth ordinary general meeting, to be held at 53, New Broad-street, E.C., on Thursday next, the 28th inst., at 3:30 p.m. :—

There has been expended on capital account during the year ending March 31, 1892, a further sum of £5,602. 9s. 2d. The gross receipts in Austria were £20,759. 14s. 5d. After providing for all expenses. including £4,655. 8s. for debenture interest and dividend on preference shares, and £3,177. 17s. 2d. for royalties and taxes to the Austrian Government, the profit on the year is £3.825, 1s. 10d., which, with the £4,485. 18s. 9d. balance from last year, gives a total of £8,311. 0s. 7d. to the credit of profit and loss account, which amount it is proposed to carry forward.

As foreshadowed in the report of last year, an agreement has been come to between the Company and the Austrian Government, for the latter to take over on December 31st next the whole of the Company's exchanges at a purchase price of 1,000,000fl., plus all sums spent on account of capital since May 1, 1891, payment to be made in cash within the first fortnight in 1893. There are other minor details to complete the agreement, which will have every attention on the part of the Board. The effect of this agreement will be the holding of a general meeting early next year to place the Company in voluntary liquidation, and to authorise the distri bution of the capital.

The Directors have again to report a continued increase in the number of subscribers to the Company's exchanges, as shown by the following table :—

	No. of subscribers.	Increase over previous 12 months.	Rental.	Increase over previous 12 months.
March 31, 1891 ..	3,023	 371	..... 239,000fl.	..... 28,000fl.
March 31, 1892...	*3,332	 309	..... 262,000fl.	..... 24,000fl.

* Exclusive of 256 "extension" telephones, which give an additional annual rental of 9,025fl.

The calls of subscribers now average 108,675 per week, as against 97,000 last year.

The Directors deeply regret to have to record the death of Dr. Eugen Weissel in December last, and desire to give expression to their deep sense of the invaluable services he rendered to the Company during the whole period of his connection with it as one of its representatives in Austria, and especially during the late negotiations with the Austrian Government for the purchase of the business. Dr. Joseph Griez de Ronse has been appointed to fill the vacancy on the Local Board in Vienna caused by the death of Dr. Weissel.

The thanks of the shareholders are again due to Mr. Krause for the very satisfactory manner in which he continues to perform his duties as General Manager.

Mr. C. L. W. FitzGerald retires by rotation from the Board, but being eligible offers himself for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths and Co., also retire, but being eligible offer themselves for re-election.

Crompton and Co. (Limited).

The following is the report of the Directors, to be presented at the annual general meeting to be held at the City Terminus Hotel, Cannon-street, E.C., on Friday next, the 29th inst., at 2:30 o'clock p.m. :—

The Directors have pleasure in submitting to the shareholders the fourth annual statement of accounts and balance-sheet made up to the 31st March last, to report that the business of the Company continues satisfactory, and that the reorganisation and additions to the Chelmsford works have proved a great advantage in increasing the output and reducing the cost of manufacture.

In order the more effectually to separate the accounts for the electric lighting of Chelmsford from the manufacturing and other accounts of the business, the Directors have caused to be registered the Chelmsford Electric Lighting Company (Limited), to which Company the installation outside the arc works has been transferred. The shares in the new Company will of course be chiefly held by this Company. The private lighting at Chelmsford is increasing very satisfactorily, and in a short time it is anticipated the new Company will be working at a profit.

The whole of the preference shares offered to the members in November last having been subscribed, the Directors now propose to issue the balance of 4,781 shares at a premium of ten shillings per share, and the members are invited to send their applications for the same to the secretary upon the form accompanying the report. This will complete the authorised issue of shares, and will provide the working capital necessary for the business as stated at the meeting last year. The premiums will be placed to reserve.

The net profits for the year amount to £15,068. 16s. 11d., and after providing for the debenture interest and other payments set out in the revenue accounts, and deducting the interim dividends already paid on both the preference and ordinary shares, there remains, with the £127. 7s. 5d. brought forward from last year, a balance available for dividend of £7,347. 7s. 4d. The Directors propose, after setting aside £750 as a provision for doubtful debts and contingencies, to declare a dividend of 3s. 6d. per share, making 7 per cent. per annum upon the preference shares, and 4s. 6d. per share, making with the interim dividend, a total of 7 per cent. per annum upon the ordinary shares, to place a further £1,000 to the reserve fund, and to carry the balance forward.

In accordance with the Articles of Association, Mr. C. F. Tufnell retires from the Board of Directors by rotation, but offers himself for re-election. The auditors, Messrs. J. H. Duncan and Co., also offer themselves for re-election.

Compagnie Française du Télégraphe de Paris à New York.

We gave in last week's *Electrician* a brief report of the proceedings at the annual meeting in Paris of this Company, held on the 12th inst. The following is an abstract of the Directors' report submitted to the meeting :—

The net receipts during 1891 amounted to fr. 1,256,930.79, and the total expenses to fr. 1,210,877.47, leaving a balance of fr. 46,053.32 ; the net receipts and the expenses showing increases as compared with 1890 of fr. 88,488.23 and fr. 131,147.74 respectively. The expenses had been sensibly diminishing during the present year, while the receipts up to May 15th showed an increase of fr. 116,000 compared with 1891.

Two interruptions had occurred during last year on the St. Pierre-Canso section of cable, and one each on the Brest-St. Pierre and the St. Pierre-Cape Cod sections, all of which had been repaired by the ss. "Mackay-Bennett."

Negotiations had been in progress with the United States Government for permission to land the Company's proposed Antilles cable in North America, and the Directors had every hope of success ; in the event of non-success the cable could be landed at St. Pierre, where no authorisation would be necessary, the island being a French possession.

The Company's appeal against the decision of the Conseil d'État in favour of the Anglo-American Telegraph Company (Limited) had not yet been reached in the Cour d'Appel, but the Directors had every hope of a favourable result whenever the case came on.

The Directors devoted considerable space in their report to a review of the circumstances leading to the attempt by the Americans to obtain command of the administration of the Compagnie française to the detriment of French interests. It was well known, the Directors said, that Mr. Mackay, the President of the Commercial Cable Company, had since 1886 acquired twenty thousand shares in the Compagnie Française, which he had made over to the Commercial Cable Company. Between the two companies an agreement was in existence in case of a breakage of either of their cables, and for six years they had been on the best terms with each other—a state of affairs suddenly terminated by the Commercial Cable Company. The Compagnie Française had had for four years a project for laying a cable between the Antilles and North America, and had been in negotiation for that purpose with the French Government and with the Société française des Télégraphes sousmarins. The total cost of the cable between New York and Puerto Plata (St. Domingo) would be seven million francs, which sum would be raised by the issue of 14,000 Five per Cent. Debentures, repayable in twenty-five years. A net annual income was estimated of fr.650,000, without taking into account the receipts from the Brazilian traffic, which it was thought would be considerable. The Commercial Company approved of the negotiations which were going on, and Mr. Mackay had interested himself in assisting to obtain for the Compagnie Française the necessary permission to land the cable at New York. There were great difficulties in the way of obtaining this permission, but in the opinion of eminent American lawyers they were not insurmountable ; and the Directors were continuing their negotiations, when in June, 1891, Mr. Mackay sent three representatives of the Commercial Cable Company (Mr. Mackay, jun., Mr. G. Ward, and Mr. Hosmer) to intimate that the latter Company did not wish the Compagnie Française to go any further with their Antilles cable project, as the Commercial Company and the Canadian Pacific Railway Company had purchased the Halifax-Bermudas Cable and would themselves make the proposed connection. The Directors absolutely declined to abandon their proposed cable, and from that moment an attempt was commenced to oust them and replace them by others more docile to Mr. Mackay's orders. The Directors appealed to the shareholders as to whether they had not done right in resisting Mr. Mackay's demands.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES DIRECTORY AND HANDBOOK, 1892, pages 308-322, *&c., &c.*]

ALBRIGHT AND WILSON (LIMITED).—This Company was registered on the 15th inst., with a capital of £400,000, divided into 1,000 preference and 3,000 ordinary shares of £100 each, to acquire and take over as a going concern the business and undertaking of Albright and Wilson, manufacturing chemists, at Oldbury, Worcestershire. The Directors include Mr. John F. Albright, of Mansion House-buildings, London, E.C., and Mr. Henry L. Wilson, of Birmingham.

CENTRAL IRONWORKS COMPANY (LIMITED).—This Company was registered on the 15th inst., with a capital of £3,000, in £1 shares, to carry on the business of iron and steel merchants, mechanical and electrical engineers, &c., at the Central Ironworks, Rockingham-lane, Sheffield.

CENTRAL RAIL TRACTION COMPANY (LIMITED).—This Company was registered on the 13th inst., with a capital of £10,000, in £10 shares, to

Digitized by Google

acquire certain Letters Patent granted to Frederick Purdon, Henry E. Walters, Basil Mott, and Patrick O'Donnell, numbered 13,351 and 13,352, for an invention for "Improvements in the Permanent Way of Railways," and for an invention for "Improvements in connection with Rolling Stock for Railways," and other rights and privileges belonging to or in connection with the said Letters Patent, and to carry on the business of electrical and mechanical engineers, machine and engineering tool makers, metallurgists, manufacturing chemists, &c.

ELECTRICAL COMPANY (LIMITED).—This Company was registered on the 13th inst., with a capital of £15,000, in £5 shares. The objects are to acquire and take over the business, assets, and liabilities of Keys Electrical Company (Limited), with a view thereto to enter into and carry into effect an agreement with the said Company and its liquidator, mentioned in Clause 3 of the Articles; to carry on the business of electrical engineers, mechanical engineers, manufacturers of and wholesale and retail dealers in all apparatus and things required for or capable of being used in connection with the generation, distribution, supply, accumulation, and employment of electricity, and contractors for the supply of electricity for all purposes. The subscribers are:—

Oscar Hertz, 56, Belsize Park-gardens, N.W.	1

The number of Directors is not to be less than two nor more than five, the first being Franz Deutsch and Felix Deutsch.

J. W. NEWTON AND CO. (LIMITED).—This Company has been registered with a capital of £10,000, in £1 shares, to acquire the undertaking of an india-rubber manufacturer, hitherto carried on by J. W. Newton and Co., at 79, Mark-lane, E.C.

JAMES SIMPSON AND CO. (LIMITED).—This Company has been registered with a capital of £250,000, in £10 shares. Object, to acquire the undertaking, property, and assets of James Simpson and Co., Limited (registered December 19, 1885); and, generally, to carry on, at the Engine Works, Grosvenor-road, Pimlico, and elsewhere, the business of engineers, machine and engineers' tool makers, boiler-makers, iron and brass founders, millwrights and metal founders.

JOSEPH SYKES BROS. (LIMITED).—This Company was registered on the 16th inst., with a capital of £100,000, in £50 shares, to acquire and carry on the business of wire manufacturers, mechanical and electrical engineers, machine and engineering tool makers, &c., carried on by the firm of Joseph Sykes Brothers, at Acre Mills, Lindley, Huddersfield.

LIRONI AND BOWMAN (LIMITED).—This Company was registered on July 13, 1892, with a capital of £2,500, in £1 shares. The objects are to acquire and take over as a going concern the business heretofore conducted by Messrs. Vittorio G. Lironi and John J. Bowman, at the Bow Electric Works, Arnold-street, Bow, E.; to enter into an agreement with V. G. Lironi and J. J. Bowman, and also with Thomas W. and Alfred J. Hollington, and to carry on the business of electrical engineers, electricians, mechanical engineers, suppliers of electricity for the purposes of light, heat, motive power, or otherwise, and manufacturers of and dealers in all apparatus and things required or capable of being used in connection with the generation, supply, accumulation, and utilisation of electricity. The first Directors are A. J. Hollington, T. W. Hollington, V. G. Lironi and J. J. Bowman.

THEATRE ELECTRICAL AND SPECIALITIES PRODUCTION COMPANY (LIMITED).—This Company was registered on the 12th inst., with a capital of £5,000, in £1 shares. The objects are to take over the business of Messrs. Gritton, Madgen, and Heald, of 28A, Leicester-square, and to carry on the business of theatrical and music-hall proprietors and managers, gas and electrical engineers and contractors, mechanical engineers, &c.

UNIVERSAL ARC LAMP SYNDICATE (LIMITED).—This Company was registered on the 16th inst., with a capital of £3,000, in £1 shares. The objects are to acquire, develop, and turn to account a certain invention of improvements in electric arc lamps, for which a patent was applied on April 13, 1892, and which is described in the provisional specification No. 7,095 of 1892; to carry on the business of an electric light and power company in all its branches, and in particular to generate, accumulate, distribute, and supply electricity, and to carry on the business of electricians, electrical and mechanical engineers, and manufacturers of and dealers in electric lamps and all apparatus and things required for, or capable of being used in connection with, the generation, accumulation, distribution, supply or employment of electricity. The subscribers (with one share each) are:—Charles H. Freedman, 66, Berners-street, W., electrical engineer; Arthur R. Carter, 4, Arthur-street, New Oxford-street, W.; Arthur H. Vesey, Cadogan-gardens, S.W., civil engineer; Frank Suter, 90, Lady Margaret-road, Kentish Town, N.W., electrical engineer; Harrington Wyman, 66, Berners-street, W., electrical engineer; James Yelloley, 15, Birdhurst-road, Wandsworth; Charles Wyman, 82, Leverton street, Kentish Town, N.W. The first Directors are Charles H. Freedman, Frank W. Suter, and Arthur R. Carter.

BRADFORD MUTUAL ELECTRIC LIGHTING COMPANY (LIMITED).—This Company, registered with a capital of £10,000, in £5 shares, to supply electric light, heat, and power to a detached block of buildings situate near Kirkgate, Ivygate, New Tyrrell-street, Hustlergate, Albion-court, and Queensgate, Bradford, Yorks, was dissolved by notice in the *London Gazette*, dated June 21, 1892.

ELECTRIC SEWAGE UTILISATION AND IMPROVEMENTS COMPANY (LIMITED).—This Company, registered in 1886, with a capital of half a million in £1 shares, to acquire, develop and turn to account certain patents and patent rights mentioned in an agreement dated October 13, 1886, made between the International Canalisation Company of Berlin, and others of the one part, and Arthur C. Woodington (for this Company) of the other part, was dissolved by notice in the *London Gazette*, dated June 21, 1892.

LEEDS AND LONDON ELECTRICAL ENGINEERING COMPANY (LIMITED).—The statutory return of this Company, made up to December 31, 1891, was filed on April 30, 1892. The nominal capital is £100,000, divided into 250 founders', 9,750 preference, and 10,000 ordinary shares of £5 each; seven shares have been taken up, but no calls have been made, the original signatories being the only shareholders.

NEW PORTABLE ELECTRIC LAMP AND POWER SYNDICATE COMPANY (LIMITED).—The following notice was filed on June 23, 1892:—"Sir: We beg to inform you that a meeting of the above-named Company was duly held on June 22, 1892, for the purpose of having an account laid before them showing the manner in which the winding up of the Company had been conducted, and the property of the Company disposed of, and the same was done accordingly. (Signed) J. H. Hays, B. Nicholson, liquidators." The Company was registered on February 2, 1887, with a capital of £9,000, in 45 shares of £200 each, to take over the business and assets of the Portable Electric Lamp and Power Syndicate Company (Limited).

WEST COAST OF AMERICA TELEGRAPH COMPANY (LIMITED).—The annual return of the above-named Company, made up to July 11th (being the fourteenth day succeeding the first ordinary general meeting in 1892), was filed on the 14th. The Company was registered on December 29, 1877, with a capital of £300,000, in £10 shares. At the time of making up all the shares had been taken up, the full amount called and all calls (£300,000) paid.

CITY NOTES, &c.

ANGLO-AMERICAN TELEGRAPH COMPANY (LIMITED).—The Board of Directors have resolved to declare an interim dividend for the quarter ended June 30, 1892, of 12s. 6d. per cent. on the ordinary stock, and 25s. per cent. on the preferred stock, less income-tax, payable on July 30th to the stockholders registered on the books of the Company on the 11th July, 1892.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—Notice is given that the coupons on this Company's Five per Cent. Debentures (1884 issue), due the 31st instant, will be paid on and after the 30th at Parr's Banking Company and the Alliance Bank (Limited), Bartholomew-lane, E.C. Coupons must be left at the banks three clear days for examination.

CASSEL GOLD EXTRACTING COMPANY (LIMITED).—In their report to March 31st last the Directors recommend a dividend of 10 per cent., and that the sum of £20,000 be set aside to form a reserve fund, leaving an undivided balance of £7,333.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended July 17th were £766, as against £689 for the corresponding period of last year, being an increase of £77. The total receipts for half-year amount to £2,262, against £2,100 in the corresponding period of 1891, being an increase of £162. A dividend at the rate of ½ per cent. per annum is recommended by the Directors of this Company on the ordinary shares for the past six months, after carrying forward the sum of £983.

ELMORE'S FRENCH PATENT COPPER DEPOSITING COMPANY (LIMITED).—A further issue is made by this Company, this time for 20,500 Perpetual Ten per Cent. Guaranteed Preference Shares of £2 each, entitled in addition to 5 per cent. (making 15 per cent.) out of the surplus profits after the ordinary shares have received 15 per cent. The 10 per cent. interest is guaranteed for the first year by Elmore's Foreign and Colonial Patent Copper Depositing Company (Limited). The present issue is payable 5s. per share on application, 10s. on allotment, 10s. on 1st September next, and 15s. on 1st October next. This issue completes the 60,000 shares authorised at a general meeting. The prospectus gives particulars of some very flattering reports from M. Secrétan, the general manager in France, and further states that since the Company has started regular manufacture good orders have been coming in, and complete satisfaction has been given to the customers. No mention is made of the objects of the present issue, applications for which close to-day (Friday) for town, and to-morrow (Saturday) for the country.

EUROPEAN GAS COMPANY (LIMITED).—At the ordinary general meeting held on Monday, the Chairman (Mr. H. McLauchlan Backler) said that they had during the past year been subject to sharp competition from the electric light, but there was evidence that those who used that light had found it more costly, and were now returning to the use of gas.

INDIA-RUBBER, GUTTA-PERCHA AND TELEGRAPH WORKS COMPANY (LIMITED).—An interim dividend of 10s. per share has been declared by the Directors.

KENSINGTON AND KNIGHTSBRIDGE ELECTRIC LIGHTING COMPANY (LIMITED).—A dividend has been declared at the rate of 6 per cent. per annum on the First Preference Shares in this Company for the half-year ended June 30th last.

Digitized by Google

MANGANESE BRONZE AND BRASS COMPANY (LIMITED).—A further dividend of 12s. per share is proposed, making a total payment for the past year of 18s. per share.

MONTREAL WATER AND POWER COMPANY (LIMITED).—Amongst the new companies whose prospectuses have been issued during the current week is the Montreal Water and Power Company (Limited). In the prospectus the supply of power is estimated to be a substantial source of revenue to the Company in the future, and it is provided for in the prospectus that the installation of a plant for 500 H.P. shall be one of the first duties of the Company after allotment.

SUBMARINE CABLES TRUST.—Notice is given that on and after the 2nd August next the balance of £1. 17s. 6d. of the coupon due in April last will be paid by Messrs. Glyn, Mills, and Co., of 67, Lombard-street, between the hours of 10 a.m. and 2 p.m. The coupons should be left with bankers for examination four clear days before payment.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The receipts of this Company for the fortnight ended July 15, 1892, amounted to £2,091, as compared with £1,973 in the corresponding period of last year, an increase of £18.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended July 15, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,559.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 741.—Vol. XXIX. FRIDAY, JULY 29, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

The number of Electrical Papers down for reading at the forthcoming meeting of the British Association at Edinburgh promises to be above the average. Thus in Section A, of which Prof. Arthur Schuster is President, Prof. Oliver Lodge will read a Paper on the "Influence of Magnetisation on the Velocity of Light," and Mr. Preece will have something to say on "Inductance." Profs. C. G. Knott and A. Schuster are respectively announced to read Papers on "The Volume Effects of Magnetisation" and "Primary and Secondary Cells in which the Electrolyte is a Gas." "A Contribution to the Theory of the Perfect Influence Machine" will be made by Mr. J. Gray; and Messrs. E. H. Barton and W. Williams will deal with "The Temperature Variation of the Magnetic Permeability of Magnetite." Prof. H. E. J. G. du Bois, of Berlin, has two Papers, one on "Leaky Magnetic Circuits," and the other on "A Magnetic Balance and its Practical Use." But the *bonne-bouche* of the meeting, we venture to prophesy, will be Prof. Ewing's magnetic curve-tracer, an instrument to which he has devoted much time and labour.

In Section G, of which Prof. W. C. Unwin is President, Mr. Preece has a Paper on "Secondary Batteries in use at the Central Telegraph Office," and Mr. Kapp has one on "Power Transmission by simple Alternating Currents." "Coal-cutting by Electric Power" will form the subject of a communication by Mr. Ll. B. Atkinson, and Mr. E. H. Woods will describe "A New Electrical Locomotive." Papers will also probably be read on telephony in the United Kingdom, and "The Human Body as a Conductor of Electricity."

The profuse promises and small performances which have characterised the revivified New Telephone Company since its new birth lent colour to the suggestion of the enemy that the whole thing was a gigantic piece of *blague*, a mere device for forcing the hand of the National Company. A perusal of our City Notes will show that such was, in fact, the case. The deliverer of the telephone renter has joined hands with the so-called oppressor, who subscribes one-third of the New Company's capital, and sends four "National" Directors to assist the deliberations of its Board.

The mean radius of supply of an electric lighting company is no such easy matter to determine, as our correspondent Mr. Cowan seems to think. We have already looked into this question; and among the statistical tables, which it is our custom to publish in our new year's number, we gave last January the gross and net area of the London companies' districts, and the plant capacity in lamps per square mile. We published on January 15th a map showing the streets in which electric mains were laid up to the end of the year, and the extent and overlapping of the districts. From these data, which we have prepared at no little trouble, our correspondent may be able to work out some such comparison. A difficulty which we perceived when calculating these tables was that the mere map of the streets in which mains are laid, and even an accurate plan of the whole network, gives no information as to the distribution of the lamps over the district. We have divided the number of supply units sold (as shown in our analysis of the Board of Trade returns) by the net area of the districts, as given in our new year's number, and the following is the result:—

	Supply units per sq. mile.
St. James	4,450,000
Kensington	575,000
Westminster	302,000
House-to-House	300,000
Metropolitan	272,000
Chelsea	257,000
Notting Hill	43,500

But this does not advance the matter much, since many of the districts were, and are still, far from being completely covered with mains.

We cannot quite agree with our correspondent that the essence of electric supply is distribution, and we think that distribution has attracted rather too much attention. Whatever the expenses of distribution may mean as given in the Board of Trade form of accounts, the average of the more prosperous London Companies for this item amounts to only 0·326d. per unit supplied. Distribution losses may mean only the C^2R losses, and no information has yet been published by means of which this waste in low-pressure or high-pressure mains, as used in practice, can be compared. If this information could be obtained it would afford a clue to the average distance of the lights from the generating centre. The losses in accumulators, resistances for regulating feeders, and dynamo losses must be deducted from the total waste in continuous-current work; and instead of the accumulator losses, the transformer losses must be taken into account in alternating-current systems in order to get at this C^2R loss.

A THOROUGH series of tests on the life and efficiency of glow lamps has been recently made at the Ohio University by Prof. THOMAS and Messrs. MARTIN and HASSLER; and a comparison of the results arrived at, with those obtained at the Central Institution, and recently published in *The Electrician*, is instructive. The instruments used seem, in each set of tests, to have been exceptionally good, and the standard of light, a Methven screen, was the same for both. The London tests were made on a few lamps only, while at Ohio no less than 127 lamps were used, but as the former were all Edison-Swan lamps, and the latter consisted of many different types, the average is probably as reliable in one case as in the other. The tests agree in regard to the efficiency obtainable with new glow lamps when run at the normal candle-power. When this efficiency is expressed in the usual way, in watts per (mean horizontal) candle-power, its value for new lamps is 4·2 for the Ohio tests, and 4·3 for the tests made at the Central Institution; in other words, 70 watts are needed to incandesce a new 16-c.p. lamp to normal brightness, if these tests are correct, and in practice the power needed must exceed this, owing to the falling off of efficiency with the age of the lamp. The usually assumed number of 64 watts thus seems too small for lamps which are really giving a light of 16 candles, although we notice, on reference to the tests reported in our issue of July 15, that *one* of the lamps, No. 202, only needed 64 watts to raise it to its full candle-power. In practice the 64 watt limit is probably not exceeded, but this indicates that the lamps are not run at their nominal candle-power. This is certainly the explanation in the case of the American lamps, for the average candle-power of the 127 lamps, tested at the normal voltage, was found to be only 14·5 instead of 16. The evidence is not so conclusive as regards the English lamps, for these, when run at the proper voltage, were found in some cases below, and in others above, the nominal candle-power.

THE decrease of efficiency with age formed the chief object of the experiments made by Prof. THOMAS and his colleagues, and the exhaustive nature of their work carried out by them may be judged from the fact that the lamps were run continuously for two months. Few reliable tests on the life of glow lamps have yet been made, so that the measurements obtained are important. We reproduce in our present issue an abstract of these tests, the net results of which are that the candle-power of a glow lamp diminishes 10 per cent. after a run of 200 hours at constant voltage, and that the efficiency in watts per candle is 4·2 for a new lamp, 5·6 for a lamp after 600 hours use, and 7 after a 1,200 hours run.

WE have, in common with several local and daily papers, received the following indignant communication with reference to the proceedings of a riverside Local Authority:—

"The Chiswick Local Board obtained some time ago a Provisional Order under the Electric Lighting Acts. Absolutely ignorant of its value, they now propose to transfer their powers for £600 in cash. But that is not all. They propose to lease a magnificent site for a station for £1 per annum. Naturally those of the inhabitants who know anything about electricity are much dissatisfied, and steps are being taken to memorialise the Board of Trade to refuse its sanction to the arrangement. The issue of the Chiswick Electric Lighting Company is likely, therefore, to be postponed for the present."

For our own part we fail to see that there is anything to complain of from the profit and loss point of view. It is not probable that anything like £600 was spent in obtaining the Order in question; so that a satisfactory profit has been made on the transaction, and the nominal rent charged for the "magnificent site" is perhaps only an offset to advantages extracted from the venturesome electric light pioneers. On the other hand, this hawking about of Provisional Orders by speculating Local Authorities, while commendable from the commercial aspect, is scarcely in keeping with municipal dignity. With the Electric Lighting Acts and the Board of Trade Regulations at their back, Local Authorities are perfectly well able to safeguard the interests of the community without going to the trouble of obtaining powers which they do not mean to make use of themselves.

Moscow Electrical Exhibition.—This Exhibition was opened on the 9th inst.

Electric Traction in Austria.—Abbazia, a seaside resort on the Adriatic, is to be connected with the main line to Fiume by an electric railway two miles long.

Erratum.—The reference on page 241 of our issue of July 8th to Vol. XXVI., page 608, for a description of the hydro-electric plant at Tivoli, should read Vol. XXVII., page 608.

Bedford.—At a recent special meeting of the Town Council it was resolved to request the Board of Trade to revoke the Electric Lighting Order which the Council had obtained.

Cable Restorations.—

	Date of restoration.
Sierra Leone—Accra	July 21.
Capetown—Mossamedes	July 22.

Appointments.—Mr. W. H. Monk, Superintendent for Telegraphs at Manchester, to be Postmaster of Great Yarmouth; and Mr. J. Haynes, Telegraph Superintendent at Gloucester, to be Postmaster of Blackpool.

Dublin.—A few of the arc lamps which have now been established in the leading streets of Dublin were lighted about one o'clock on Wednesday for the purpose of testing the light. The experiment was a great success.

St. Pancras Vestry.—The electric light is to be further extended in St. Pancras. The Electric Light Committee of the Vestry have resolved to light Hampstead-road to High-street, Camden Town, one mile in extent, at a cost of £4,750.

Islington Vestry.—This vestry held a special meeting on Friday last to consider a report from Prof. Henry Robinson with reference to the electric lighting of their district, and it was unanimously resolved to apply for a Provisional Order.

Electric Lighting at Shanghai.—According to the *North China Daily News*, the Municipal Council of the Anglo-American Settlement at Shanghai have announced that no further permits will be granted for any extension of overhead wires, under any circumstances whatever; and the Council has been informed by the Company that it cannot put its wires underground.

The Electrical Utilisation of Water Power in France.—The little town of Dourgne, in the Department of the Tarn, has recently municipalised the water of Touron rivulet. Under ordinary circumstances this little stream only yields 15 to 18 litres per second (3·3 to 4 gallons per second); but a dam 20ft. high has given a reservoir of 1,500 cubic metres (53,000 cubic feet) capacity, and a 214ft. fall is obtained.

Mr. F. N. Gisborne.—In reference to the account of the death of Mr. Cyrus W. Field, which recently appeared in this Journal, it is interesting to note that only one survivor now remains of the group of incorporators in the famous Charter of 1854, of the New York, Newfoundland, and London Telegraph Company, viz., Mr. F. N. Gisborne.

Digitized by Google

Personal.—At the Technological Examination held last May by the City and Guilds of London Institute, the Cordwainers' Prize and the Silver Medal were gained by Mr. Conrad K. Falkenstein, in the Tanning Section (Honours). Mr. Falkenstein has been devoting his attention during the last three years to the applications of electricity in the tannery, with the British Tanning Company.

Electric Traction Schemes in Paris.—The Conseil Municipal has adopted the proposed Berlier electric tubular railway scheme. A security of £20,000 will have to be deposited; there is to be a uniform fare of 2d., and no *employé* is to be paid less than 7d. an hour. The Government, it is stated, hold that the action of the municipality is *ultra vires*, and that the Legislature must be asked to give its sanction to the scheme.

Reciprocity.—Electricians have generally supplied themselves with gas in their boiler and engine rooms as a standby; but it has been reserved for Mr. Craven, the manager of the Corporation Gas Works at Dewsbury, to introduce the electric light into the pumping room. A small dynamo has been belted on to one of the pumping engines, and it gives all the light wanted with safety, and at no cost. This practice is being followed in various other places. This is a sign of the times. Even gas engineers are now embracing electricity.

Wolverhampton.—The Town Council have for some time been considering the advisability of putting into operation the powers conferred upon them by their Electric Lighting Order. The Lighting Committee prepared a report which has been submitted to a private meeting of the Council, and the scheme has been unanimously adopted. The price of the unit is taken at 6d., and the report of the Borough Surveyor and Mr. Harold Dickinson contain recommendations involving an expenditure of £37,000. It is proposed to immediately erect a 10,000 light station with an ultimate capacity of 50,000 lights.

The Preservation of Accumulator Plates.—The following is M. G. Darrieus' recipe for keeping the plates of accumulators in a healthy condition when the cells are left idle for a long time. After being well charged, the plates should be carefully washed, and then placed in a neutral solution of sulphate of soda. Before use they should be charged *in* the sulphate of soda, and then replaced in a sulphuric acid solution. "An already lengthy experience of this process," says M. Darrieus in *L'Industrie Electrique*, "enables me to strongly recommend it."

A Workshop Wrinkle.—The use of an electric arc, as employed in the Benardos welding process, may be often adapted for other purposes in which a local application of heat is required. A correspondent writes to the *English Mechanic*, describing the breaking of a tap in a ½in. hole in the end of a shaft. After trying unsuccessfully to soften it with a blowpipe, he connected the shaft to a dynamo, and forming an arc with a carbon, a current of 30 to 40 amperes brought the end of the shaft to a dull red in about three minutes. When cooled the tap was easily drilled out.

Communication with Lighthouses.—The Royal Commission for inquiring into electrical communication with lighthouses and lightships met again on Thursday last week, at 21, Northumberland-avenue. Lord Mount-Edgcumbe presided. After considering the various methods proposed for the establishment of communication by telegraph with lighthouses and lightships on the Scotch coast, the Commissioners decided to make a tour of inspection of lighthouses, beginning in the latter part of August at the Goodwin Sands and the mouth of the Thames, and proceeding along the coast to Cromer. Visits will also be made to the Bristol Channel and the Scilly Isles.

Dover.—The following is the gist of the agreement come to between the Town Councils of Canterbury and Dover and the Brush Electrical Engineering Company, alluded to on p. 299 of our last issue. The name of the Company is to be "The Dover and Canterbury Company." Two accounts are to be kept, and the chief office is to be at Dover. It was agreed to allow the Company to debit the annual accounts with 7½ per cent. for depreciation until a sum equal to one quarter of the capital has been reached. In the matter of the accumulated dividend this is to be 10 per cent. before a reduction of price to consumers becomes compulsory. The penalty to be paid by the Company for lamps out will be 5s. per lamp per night.

Electric Lighting on Shipboard.—Considerable capital has been made in some quarters out of the recent accident on the French battleship, "Dupuy-de-Lôme," the extinction of the electric light, it was alleged, being the cause of the accident. According to *La Lumière Electrique*, the facts of the case were as follows:—One of the boiler stays having yielded 15mm., there was an escape of steam. A panic ensued, and the stokers precipitated themselves towards the ladders, and three gauge-cocks somehow got opened. The steam invaded the dynamo room, and the attendant, thinking discretion the better part of valour, shut down the dynamos and electric steering gear apparatus and departed, with the result that the ship was left in darkness and unmanageable.

The Physiological Effects of Sinusoidal Currents.—In a recent communication to the Académie des Sciences, M. d'Arsonval states that, according to experiments made by him, it would appear that by spreading out the sinusoidal current curve we may pass fairly strong currents through the human body without causing pain, muscular contraction, or chemical action. This absence of all physiological action is, however, only apparent, since analyses of the respiratory gases show that the passage of the current is accompanied by an increased absorption of oxygen and an increased elimination of carbonic acid. By augmenting the frequency powerful muscular contractions are provoked, which are, however, less painful than those caused by the irregular variation of an induction-coil current.

A Real Electric Locomotive.—"It has yet to be proved," says the *Engineer*, "that it is possible to make an electric motor which will comply with all the multifarious conditions inexorably dictated by the exigencies of traffic. In the United States nothing of the sort has yet been produced, and it is fair to assume that they know as much at the other side of the Atlantic as is known at this about electricity. Apparently a very wide departure from existing methods and principles of construction may be needed to secure success, and no one can say that the field of invention in this direction is nearly filled. It seems, however, to be almost time that someone with the requisite knowledge and ingenuity set himself in earnest to the work of designing a real electrical locomotive."

Packing Machinery.—Whitelead and tallow is commonly used to protect bright parts of machinery in transit; but neither this nor the specially-prepared greases will stand a voyage to Brazil, Chili, South Africa, or Australia. Tropical heat either hardens the protective substance, so that it becomes very difficult to remove, or it fails to hold, and blisters or scales off. In the "Machine-shop Notes" of the *Engineering Magazine* of New York for this month directions are given for making "tar-lined" boxes. "Kiln-dried pine lumber" may, perhaps, be used in this country, but not under such a name; the pieces are to be "cleated," probably meaning dowelled together, and the sides are to be painted with "hot rock asphaltum." While hot, thick tough paper is to be pressed on to the pitch, and a second coat is to be applied hot both to the interior and between the joints.

Electric Lighting Notices.—Notices of intended application for Electric Lighting Provisional Orders have been served upon the following Local Authorities by the following Companies:—Cork Town Council, Cork Gas Consumers' Company; Newmarket Local Board, British Electric Light Company; Rotherhithe Vestry, County of London Electric Lighting Company; St. George's-in-the-East Vestry, County of London Electric Supply Corporation; Weymouth Town Council, Aurora Electric Lighting and Distribution Company; Ryde Town Council, Aurora Electric Lighting and Distribution Company. This Company proposes to supply electricity at 6d. per B.T.U. The recommendation of the Public Works Committee that the application be refused has been adopted unanimously, it being explained that the object of the resolution was merely to give the Council a *locus standi*.

Town Councils and Electric Lighting.—The following extracts from a circular, emanating from the Town Clerk's

Digitized by Google

office, Wigan, may be taken as a sample of the way in which electric lighting enterprise is often covertly snuffed out by Local Authorities in possession of Electric Lighting Orders which they neither wish to make use of themselves or allow others to use :—

Dear Sir: You are doubtless aware of the fact that in 1890 the Corporation obtained a Provisional Order for the supply of electric lighting to the town; but as it did not appear at the time the powers were granted to be any general desire on the part of the public to have such light in preference to cheap and good gas, no electric works were laid down by the Corporation. They think it right, however, to state that they are prepared to undertake the supply in the following streets . . . if such be the wish of the ratepayers, subject to all the restrictions imposed by the Provisional Order for ensuring safety and efficiency. I am, therefore, to inquire whether you will agree to take the electric lighting if provided by the Corporation for a fixed period of three years, at a reasonable price, say 6d. per unit, or double the price of gas-light per light. To lay down suitable plant will be costly, and you, as a ratepayer, would not like the expense to be incurred unless there is a reasonable prospect that it will not be a serious loss. Your early reply on the enclosed postcard will be esteemed a favour, so as to enable the Corporation to determine as to what course they should adopt.

The Gresham University.—The Committee formed last January to oppose the grant of the Gresham University Charter have drawn up and submitted to the new Royal Commission a memorandum embodying the points which, in their opinion, are of special importance for the satisfactory construction of any new scheme. It is suggested that the Council should include, in addition to nominees of the Crown, a representation of the teaching staff of the institutions in London giving teaching of University rank. The Professors and other teachers of the University should be grouped into Faculties, with such consultative and administrative powers as shall be determined by the Council, the examiners of the University to be members of the Faculties *ex officio*. It is proposed that there shall be a strong Professoriate, with a sufficient staff of lecturers and demonstrators. The appointment of University teachers should be vested in all cases not in the Colleges, but in the Crown or in the University itself, either directly through the Council or through electing Boards appointed for the purpose. If the University is to do any considerable work it is pointed out that there must be liberal assistance from public sources, such as the Consolidated Fund, the County Council Funds, the City Companies, and the City Parochial Charities. It is suggested that the existing University of London should be remodelled, and that the new University should be empowered to confer degrees in theology.

The Rival (?) Telephone Companies.—An esteemed correspondent writes us as follows :—

"The New Telephone Company, which has this week emerged into a new phase of existence, has had a strangely chequered career. Founded in 1884 to work the 'Valve' Telephone of Prof. S. P. Thompson, it succeeded in gradually establishing a business in the sale of these instruments, and of a modified form devised by Mr. White, in the teeth of the opposition of the United Telephone Company, who then held the Bell and Edison patents, and had established a reign of terror over all rivals. In 1889, however, just as the New Telephone Company's affairs were blossoming into success, it was sued by the United Telephone Company for infringement, it being alleged that the White pattern of transmitter was within the Edison patent. Without defending the action, the New Telephone Company's Directors succumbed at once, and were compelled to surrender not only the instruments attacked, but also all their 'valve' transmitters of older pattern and all their receivers. To avoid vexatious litigation, the New Company went into liquidation, but after some months paid its trade creditors in full, and the liquidation was annulled. At this stage their affairs, and their principal asset—the licence of the Postmaster-General—passed into the hands of new Directors, who proceeded to reconstruct the Company, and to inaugurate a more vigorous policy. They entered into an agreement with the City of London Electric Lighting Company for the use of its spare ways and conduits underground in the City. They acquired the Mutual Exchange at Manchester. They entered into negotiations with other electric lighting companies in London for underground wayleaves. The National Telephone Company, foreseeing the crisis which its resuscitated rival would assuredly provoke when its underground service with twin-wires should be completed, hastened to make terms with its once-vanquished competitor. It has not only subscribed for one-third of its capital, and agreed to allow the subscribers of the New Telephone Exchange to connect up to those of the existing exchange, but has even sent four of its Directors to join the new Company's Board. The next development will be awaited with some interest."

The Electrolysis of Silver Nitrate in Vacuo.—In a Paper recently read before the Royal Society, Prof. Schuster and Mr. A. W. Crossley state that they undertook some investigations in order to clear up some minor irregularities which occur in the measurement of current by means of the silver voltameter. These anomalies are the slightly heavier deposit obtained from a warm solution and the discrepancy between deposits taken simultaneously in platinum bowls of different sizes. The Paper dealt, however, mainly with the fact discovered by the authors that deposits obtained *in vacuo* are somewhat larger than when the electrolysis is conducted in voltameters exposed to air at the ordinary pressure. The authors trace this difference to the effects of dissolved oxygen, for when the electrolysis was carried out in an atmosphere of oxygen the deposits were less than those obtained in air. The apparatus employed to obtain a deposit *in vacuo* was an inverted bell jar, closed at the bottom by a rubber stopper, at the top by a plate of glass. The jar contained a tight-fitting cylindrical cage of wire gauze. The platinum bowl was placed on two copper rods, soldered to the cage, to which one of the battery wires was connected. The anode was suspended from a glass rod. The large platinum bowl was 5in. in diameter, and the small one 3½in., the anodes were about 2mm. thick. The authors obtained a consistent difference of about 0·02 per cent. in favour of the larger bowl. Some experiments seemed to show that when *anodes* of the same size are used this discrepancy disappears, confirming the impression of the authors that the effect may possibly be due to secondary products found at the anode when the current density exceeds a certain value. The results of similar experiments *in vacuo* were not very concordant; but the average deposits were heavier in the large bowl. The electro-chemical equivalent of silver as deduced from electrolysis *in vacuo* was almost identical with that obtained in Lord Rayleigh and Mrs. Sidgwick's deposits from hot solutions. The experiments showed a small but very consistent polarisation of seven millivolts, which was the same in air and *in vacuo*. The authors conclude from their experiments that the true electro-chemical equivalent of silver is probably not quite one part in a thousand greater than the value given by Lord Rayleigh.

Ceylon as a Source of India-Rubber Supply. — At the London Chamber of Commerce on Monday last Mr. J. Ferguson, the corresponding Secretary to the Colonial and Imperial Institutes in Ceylon, gave an address on "Tropical Agriculture in that Colony." Dealing with the india-rubber plant, he thought there was much encouragement for the Ceylon planter to take up this product, for which he understood there was a large and growing demand at remunerative prices, especially as the prospects of the supply from South America, Africa, and the East (nearly all forest trees), was gradually falling off, or at any rate was below the requirements of manufacturers. If it was true, as he had learned, that one province of Para in Brazil had developed an export equal to 17,000 tons per annum in a favourable year, and worth £300 a ton, or £5,000,000, all the rubber being got from systematic tapping of the trees, there ought certainly to be room in Ceylon for extensive planting experiments with a view to the supply of the future. In Ceylon no little attention had been given to the cultivation of caoutchouc, or india-rubber, trees over a dozen years ago, when they had been hard pressed for products to take the place of coffee; and for some years great hopes were expressed that the industry would become a profitable and permanent one. Sample parcels of Ceylon Ceara rubber harvested from trees eight to ten years old, sold as high as 4s. per pound. But the great rush into tea, and the greater ease with which returns could be got from that product, together with the long time required by rubber trees to mature, and the greater expense in tapping and harvesting, discouraged further planting; and he could not speak of more than 450 acres in all Ceylon as now being cultivated with rubber plants, although of late years Dr. Trimer had been able to report very favourably on experiments under his direction in the Botanical Gardens, and attempts were now being made by the Ceylon Forests Department to grow the tree in jungle clearings. The Gardens had also sent plants and seeds to North Borneo and East Africa. In Colombo they had endeavoured to bring all the information about rubber into a Planters' Manual, and there could be little doubt that if the Ceylon Garden and Forest experiments went on well during the next few years, planters would once more take up the industry.

ELECTROMAGNETIC THEORY.—XXXIII.

BY OLIVER HEAVISIDE.

(*Continued from page 275.*)

§ 153. All the above analogies, however good or bad they may be in other respects, are deficient in one vital property, inasmuch as they involve the elasticity of distortion, and with it, the energy of distortion. But the electromagnetic equations, especially when put in the duplex form symmetrical with respect to the electric and magnetic sides, have nothing in them suggestive of distortional forces, nor can we represent either the electric or the magnetic energy as the energy of distortion. On the other hand, the equations are fully suggestive of rotation. If, then, the elastic solid has still to do duty for purposes of analogy, and yet not fail upon the point mentioned, it is clear that the rigidity must be done away with, at least as an electromagnetically active influence. Its place must then be taken by elastic resistance to rotation, by using a rotational instead of a shearing stress. This brings us to the medium invented by Lord Kelvin, called by him simply Ether, and contrasted with Jelly, which means an incompressible elastic solid with ordinary rigidity. This rotational ether has mass of course, for one thing, which brings in kinetic energy (of translation); and, on the other hand, it possesses, by means of internal arrangements with which we are not immediately concerned, the property of elastically resisting rotation, and consequently stores up energy of the potential kind, to balance the kinetic. If this were all, there would be little more to say. But Lord Kelvin found that his Ether enabled him to complete a long-delayed work, viz., to produce a satisfactory elastic-solid analogy to suit the problem of magnetic induction ("Mathematical and Physical Papers," Vol. I., art. 27, and Vol. III., art. 49); and I have pointed out that this rotational ether enables us to construct good all-round analogies for the propagation of disturbances in a stationary dielectric (Appendix to chap. II., *ante*), with correct localisation of both energies and of the flux of energy. As these are the only all-round elastic-solid analogies yet known, we may here consider them again, especially in relation to the previously given analogies, and to show where the changes come in.

Go back to equation (313), giving the translational force $\mathbf{F}$ due to the stress in an elastic solid when there is rotational elasticity as well as rigidity. We have

$$\mathbf{F} = n(\nabla^2\mathbf{G} + \tfrac{1}{3}\nabla \operatorname{div}\mathbf{G}) + k\nabla \operatorname{div}\mathbf{G} - \nu \operatorname{curl}^2\mathbf{G}, \quad (346)$$

where $\mathbf{G}$ is the displacement, n the rigidity, k the compressive resistivity, and ν the new elastic constant connected with the rotation. Now, we have $\operatorname{curl}^2 = \nabla \operatorname{div} - \nabla^2$, so we may rearrange (346) thus,

$$\mathbf{F} = (n+\nu)\nabla^2\mathbf{G} + (k + \tfrac{1}{3}n - \nu)\nabla \operatorname{div}\mathbf{G}, \quad . \quad (347)$$

and this may be split up into circuital and divergent parts, viz.,

$$\mathbf{F}_1 = (n+\nu)\nabla^2\mathbf{G}_1, \quad \text{(circuital)}, \quad . \quad (348)$$

$$\mathbf{F}_2 = (k + \tfrac{4}{3}n)\nabla^2\mathbf{G}_2, \quad \text{(divergent)}. \quad (349)$$

Now observe that in the circuital equation, n and ν occur additively, so that equal parts of each have the same effect, and either may be replaced by an equal amount of the other. This is irrespective of the compressibility, which is not concerned in circuital disturbances. We see, then, that the rigidity may be done away with altogether and equal ν substituted, without affecting the propagation of circuital disturbances. This is a very remarkable property.

Observe, also, that in the divergent equation ν does not enter at all, although n does, and in the same way as in the ordinary compressible rigid solid. In fact, the coefficient $k + \frac{4}{3}n$ is the same as the former $m+n$, of § 142 and later. So the propagation of divergent disturbances is the same as if the rotational elasticity were done away with.

Now, we have already noticed the case in which the speed of the divergent wave is brought down to zero—the contractile ether of §§ 142, 143. In an ordinary rigid solid, which was then referred to, this requires negative compressibility. But now, if n be abolished and ν substituted, so that the circuital propagation is unaffected, the divergent equation will contain only k, so that to make the speed of the divergent wave zero we need only abolish the resistance to compression, or make $k=0$. The medium does not now resist either change of shape or of size, but resists rotation only, and the potential energy is the energy of rotation. This is one extreme form of the rotational ether, made by combining it with the contractile, by the evanescence of the rigidity and of the resistance to compression. The medium is quite neutral as regards expansion and compression.

Now, it is clear, from equation (348) and matter in previous paragraphs, that we may construct analogies to suit the non-conducting dielectric by abolishing n and using ν instead, without concerning ourselves with k at all, which may have any value from zero to infinity. But Lord Kelvin's ether is got by going to the other extreme from the neutral case just mentioned.

§ 154. Take $k=\infty$ (with $n=0$) making the medium incompressible, and therefore making disturbances in an unbounded medium be necessarily circuital, whether the impressed forcive be circuital or not. We now have

$$\mathbf{F}_1 = \nu\nabla^2\mathbf{G}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (350)$$

by (348), whilst the other equation (349) will merely assert that $\mathbf{F}_2$ is balanced by difference of pressure. This we are not concerned with, since our impressed forcive should be circuital in the electromagnetic comparisons. The stress (310) is now

$$\mathbf{P}_N = -\nu\mathbf{V}\mathbf{N}\operatorname{curl}\mathbf{G}, \quad . \quad . \quad . \quad . \quad (351)$$

where we ignore the uniform pressure for the reason mentioned. The torque accompanying this stress is, by (311),

$$\mathbf{S} = 2\nu \operatorname{curl}\mathbf{G}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (352)$$

and the translational force is

$$\mathbf{F} = -\operatorname{curl}\tfrac{1}{2}\mathbf{S} = \nu\nabla^2\mathbf{G}, \quad . \quad . \quad . \quad (353)$$

agreeing with (350). So the equation of motion is, by (306),

$$\mathbf{f}_1 = (\rho p^2 - \nu\nabla^2)\mathbf{G} = (\rho p - \frac{\nu}{p}\nabla^2)\mathbf{q}, \quad . \quad . \quad (354)$$

where $\mathbf{f}_1$ is the circuital impressed force, and $\mathbf{q}$ is the velocity. As before, we keep to small motions in general.

Equation (354) may be at once compared with the electromagnetic

$$\mathbf{f} = \left(\mu p - \frac{\nabla^2}{cp}\right)\mathbf{H} = \left(\mu p^2 - \frac{\nabla^2}{c}\right)\mathbf{Z}, \quad . \quad . \quad . \quad . \quad . \quad (355)$$

as in (325), (326), our first example, and we therefore deduce the following correspondences:—

	$\mathbf{Z} = \mathbf{H}/p$	stands for	$\mathbf{G}$,	(spacial displ.)
(mag. force)	$\mathbf{H}$	,,	,, $\mathbf{q}$,	(velocity).

(energy flux)	$\mathbf{V}\mathbf{E}\mathbf{H}$	,,	,, $\mathbf{V}\frac{1}{2}\mathbf{S}\mathbf{q}$,	(energy flux)

Referring to the similar list in § 146, it will be seen that the correspondences there given are repeated here, except that the elastic constant changes its meaning, and that there are now additional correspondences. The electric energy is correctly localised by the potential energy of the rotation. Since the kinetic energy is also correctly localised, we need not be surprised to find that the energy-flux has the same distribution.

The activity of the stress $\mathbf{P}_N$ is $\mathbf{P}_N\mathbf{q}$ per unit area, which is the same as $q\mathbf{N}\mathbf{P}_q$, if $\mathbf{P}_q$ be the stress on the plane whose normal is $\mathbf{q}$, provided the stress is irrotational. But if rotational, as at present, it is $q\mathbf{N}\mathbf{Q}_q$, where $\mathbf{Q}$ is conjugate to $\mathbf{P}$. This activity means energy transferred from the side of the plane when the stress vector is reckoned, to the other side, or against the motion. The vector expressing the energy flux is

Digitized by Google

therefore $-q\mathbf{Q}_q$, not counting the convective flux. In our present case, by (351), $\mathbf{Q}$ is the negative of $\mathbf{P}$, because it is purely a rotational stress, so $\mathbf{W}=q\mathbf{P}_q$ is the vector flux of energy; or, by (351),

$$\mathbf{W}=-\nu q\mathrm{V}\mathfrak{q}_1\operatorname{curl}\mathbf{G}=-\nu\mathrm{V}\mathfrak{q}\operatorname{curl}\mathbf{G}, \quad . \quad (356)$$

which is, by the above table, the same as $\mathbf{VEH}$, the electromagnetic flux of energy. (In the above, q and $\mathfrak{q}_1$ are the tensor and unit vector of $\mathfrak{q}$.)

The above reasoning is applied directly to the unit element of volume. But it may be easier to follow by taking any volume into consideration. If $\mathbf{N}$ is the normal outwards from the surface enclosing it, then $\mathbf{P}_N$ is the pull, per unit area, of the matter outside, on the matter inside the surface, across the unit area of the interface; and $\mathbf{P}_N\mathfrak{q}$ is its activity. The total activity of $\mathbf{P}_N$ all over the surface is therefore $\Sigma\mathbf{P}_N\mathfrak{q}$, which is the same as $-\Sigma\mathbf{N}q\mathbf{P}_q$, and expresses the work done per second by the matter outside on the matter inside the surface, or the rate of transfer of energy from the outside to the inside; and its equivalent is the rate of increase of the stored energy, potential and kinetic, within the surface. The convergence of the vector $q\mathbf{P}_q$ expresses the same property for the unit volume, so that $q\mathbf{P}_q$ is the flux of energy (per unit area) itself. (The small convective flux of energy is ignored here.)

§ 155. That *any* circuital flux of energy may be superadded, without making any difference in the transformations of energy, is a fact which is of importance as evidence against the objectivity of energy, but is of no moment whatever in the practical use of the idea of a flux of energy for purposes of reasoning. We should only introduce an auxiliary circuital flux when some useful purpose is served thereby.

I may here remark that (speaking from memory) when Professor J. J. Thomson first objected to the $\mathbf{VEH}$ formula as representative of energy-flux, by reason of the circuital indeterminateness, he added that a knowledge of the real flux could only be determined from an actual knowledge of the real dynamical connections involved, that is to say, by a knowledge of the mechanism. But this is surely an inconclusive argument, because the circuital indeterminateness applies even then. In fact, it is universal in its application, as energy is at present understood. For there to be an absolutely definite flux of energy through space seems to require energy to have objectivity in the same sense as matter, which is a very difficult notion to grasp, and still more difficult to accept. But even if it be accepted, the argument of circuital indeterminateness remains in action, when it is desired to find what *is* the flux in a given case.

In a recent number of the *Phil. Mag.*, Mr. Macaulay, by the addition of a certain circuital flux to $\mathbf{VEH}$, brings out the result that in stationary states the modified flux reduces to $p\mathbf{C}$, where p is potential and $\mathbf{C}$ current-density. I am, however (unless I forget much of what I have learnt in the last 15 years), unable to see that the auxiliary flux proposed serves any useful purpose. In the first place, it greatly complicates the flux of energy in general, and is entirely against the more simple ideas to which we are naturally led in the study of electromagnetic waves, whether in dielectrics or conductors. Besides that, it is implied that the function p, or electric potential, is a determinate quantity specifying some definite state of the medium. This seems to me to be an idea which has no place at all in Maxwell's theory. It may have place in other theories, but that is not to the point. To exemplify, put a closed circuit (with battery) supporting a steady current inside a metal box, and electrify the latter from outside. According to the $p\mathbf{C}$ formula, the flux of energy in the wire suffers a very remarkable change, by reason of the raising of the potential of the box and its interior. But, according to the interpretation of Maxwell's scheme which I expound, there is no change whatever in the electrical state of the interior of the box in the steady state (though there may and must be a transient disturbance in the act of charging it, which is a separate question), and the energy distribution and its flux are the same as before, because $\mathbf{E}$ and $\mathbf{H}$, which settle the state of affairs, electric and magnetic, are unchanged. There are, however, I believe, some electricians who will be much gratified with the $p\mathbf{C}$ flux in steady states.

The total flux of energy through a wire will be $p\mathrm{C}$, where by C we mean the total current, obtained from $p\mathbf{C}$ by integration over the cross-section. Now this is somewhat suggestive of my expression VC for the total flux of energy along a circuit of two conductors. But there are radical differences. For VC is the integral form of $\mathbf{VEH}$ in the dielectric. Although C in VC means the same as in $p\mathrm{C}$, being the circuitation of $\mathbf{H}$, or the gaussage, V has no connection with p the potential, for it (V) is the line-integral of $\mathbf{E}$ across the circuit from one wire to the other—*i.e.*, the transverse voltage. Again, the VC formula holds good in variable as well as in steady states, whilst the proposed $p\mathrm{C}$ holds for steady states only. Even in steady states, when V specializes itself and becomes difference of potential, it remains different from p.

But although I cannot see the utility of the proposed change, which seems to be a retrograde step, I think that Mr. Macaulay's mathematics, which is of a strong kind, may be of value in the electromagnetic field in other ways, especially when cleared of useless and treacherous potentials.

§ 156. Returning to the suppositional Ether, the conception is of an incompressible medium possessing mass, which involves translational inertia, and therefore kinetic energy, and which elastically resists rotation, and so stores potential energy; and we have supposed that the velocity of the medium means magnetic force, and that its density means μ, so that the kinetic energy and the magnetic energy are compared. But we may equally well have this comparison of the energies combined with a different interpretation of μ. Take, for instance, the induction to mean velocity. Then, since the magnetic energy is $\frac{1}{2}\mu^{-1}\mathbf{B}^2$, we see that it is now, not μ, but μ^{-1} that is the density, whilst $\mathbf{H}$ is momentum. Also, since $\mu c v^2=1=\rho\nu^{-1}v^2$, we see that the new interpretation of c is νv^{-2}. That is, the change of μ from density to its reciprocal involves the change of c from compliancy to its reciprocal, multiplied by v^{-2}, making ρ^2/ν. But it is better to write them out side by side, thus:—

(mag. energy)	$\frac{1}{2}\mu^{-1}\mathbf{B}^2$	stands for		$\frac{1}{2}\rho\mathfrak{q}^2$,	(kin. energy).
(induction)	$\mathbf{B}$	,,	,,	$\mathfrak{q}$,	(velocity).
(reluctivity)	μ^{-1}	,,	,,	ρ,	(density).
(mag. force)	$\mathbf{H}$	,,	,,	ρq,	(momentum).
(el. current)	$\operatorname{curl}\mathbf{H}$	,,	,,	$\rho\operatorname{curl}\mathfrak{q}$,	
(el. displ.)	$\mathbf{D}$	,,	,,	$\rho\operatorname{curl}\mathbf{G}$,	
(permittivity)	c	,,	,,	$\nu^{-1}\rho^2$,	
(el. force)	$\mathbf{E}$	,,	,,	$\nu\rho^{-1}\operatorname{curl}\mathbf{G}$,	
(el. energy)	$\frac{1}{2}c\mathbf{E}^2$	,,	,,	$\frac{1}{2}\nu(\operatorname{curl}\mathbf{G})^2$	(potl. energy).

The potential energy still correctly localising the electric energy, in spite of the other changes, we may expect the flux of energy to be correct. We have

$$\mathbf{VEH}=\nu\rho^{-1}\mathrm{V}\operatorname{curl}\mathbf{G}.\rho\mathfrak{q}=-\nu\mathrm{V}\mathfrak{q}\operatorname{curl}\mathbf{G},$$

as before, equation (356).

Similarly, we may assume that μ is not the density, nor its reciprocal, but an unstated function of the density, say $\mu=f(\rho)$, and work out the various correspondences that this necessitates. We shall, for example, by the formulæ for magnetic and kinetic energy, require

$$\mathfrak{q}=\mathbf{H}\{\rho^{-1}f(\rho)\}^{\frac{1}{2}}.$$

Of course, in thus comparing magnetic with kinetic energy, we shall always have $\mathbf{H}$ compared with $\mathfrak{q}$, or with some multiple of $\mathfrak{q}$, which may change its "dimensions," as, for example, in the above detailed cases, where $\mathbf{H}$ is changed from velocity to momentum.

Corrections.—In equation (319), for $\mathbf{D}$ read $\mathbf{G}$. In (320) and (321), delete the $\frac{1}{2}$ before ν_1 and k_1.

(To be continued.)

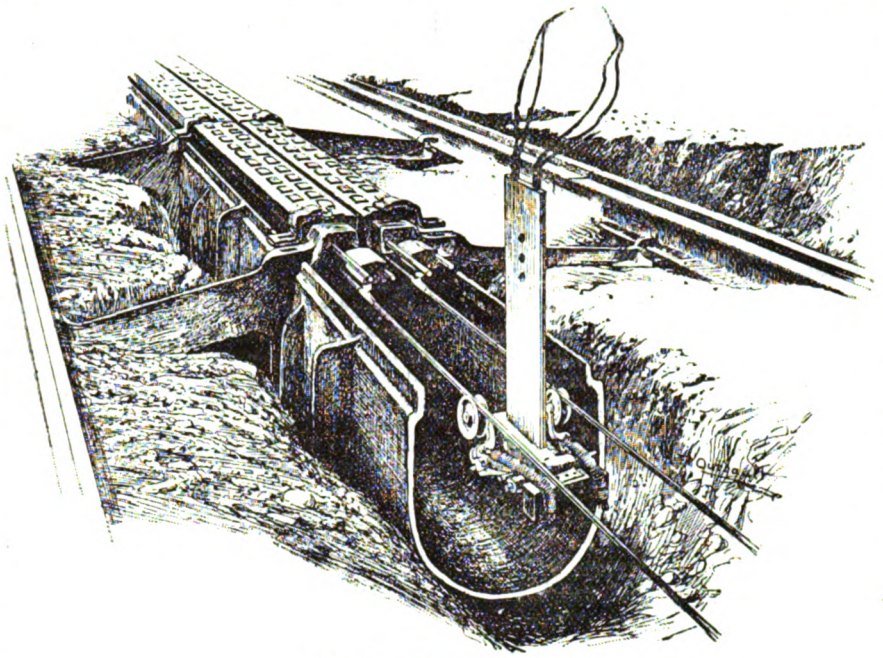
THE LOVE ELECTRIC TRACTION CONDUIT.

While the hot battle for and against the overhead trolley has been going on between the street car companies and the Municipal Authorities in various cities, resulting, in New York and Chicago, in the adoption of the cable, a street car company in the latter city has, says the *Electrical World*, been

Digitized by Google

experimenting quietly with a conduit electric road in order to satisfy itself on the question of the possibility of working such a road successfully. This road has now been running some months.

The conduit used is that known as the Love system. One of the important features is that the top cover of the conduit (*see* Fig.) consists of rolled steel strips or angle irons, having a deep vertical flange on the side bounding the slot. These angle-irons are laid in long lengths, being secured in place by the clamps shown; by releasing these fastenings, which is a very simple matter, the angle-irons are readily removed, which opens the conduit and renders it easily accessible for examining and repairing the wires, cleaning the conduits, and other purposes. The flange on the slot side extends lower down than the wires, and therefore protects them in a measure from interference. It will be noticed, too, that both lead and return are insulated. One of the parts which was very troublesome at first was the trolley itself; but the simple form of trolley shown, which is the one used now, is perfectly satisfactory. The trolley wheels are slightly smaller than those used on overhead roads, and are loosely supported so as to admit of a small amount of play in all directions, just enough to adapt themselves to the inevitable slight irregularities, chiefly at curves. The whole trolley bar is easily detached and replaced if broken. The conduit is well drained by means of frequent pipe connections to the sewers and settling boxes. In order to clean it of mud and other sediment, a brush is attached to the trolley, which sweeps the dirt into receiving boxes.

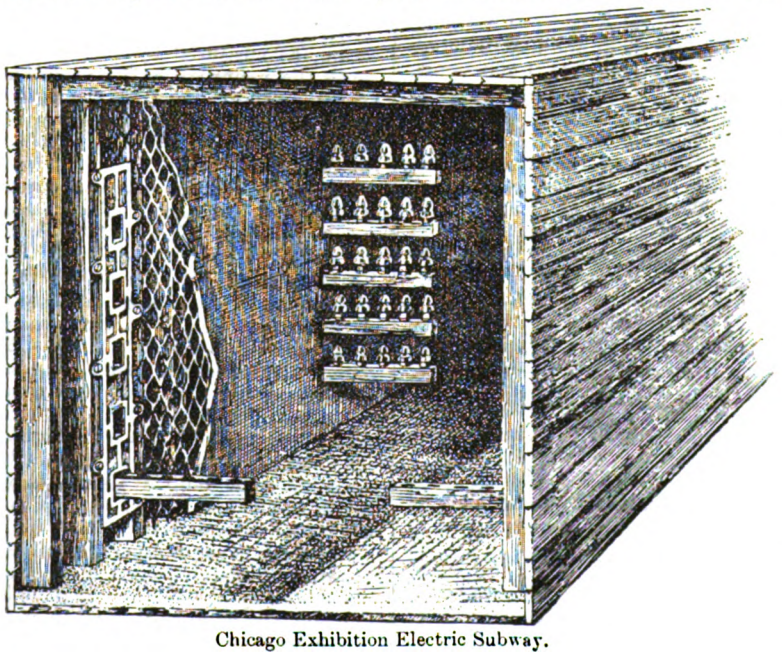


The Love Electric Conduit.

The road is one and five-eighth miles long, embracing four curves of 35°, 45°, and 55° radius, two double and two single track crossings and 10 switches. It was built during the past winter on the tracks of the North Chicago Street Railway Company. That the road has been running successfully is best shown by the fact that the North Chicago Street Railway Company has accepted the road. In a letter from President Yerkes, of that Company, he says:—"So far as the system itself is concerned it gives us perfect satisfaction, and contrary to my fears the insulation is not interfered with in any manner by moisture. We have had some of the most severe rains in this vicinity during the past three or four months that I have ever experienced, so much so that at one time the cars ran through water on the track three or four inches deep, the trolley in the conduit running in the water, owing to the inability of the sewer connections to carry off the flood fast enough, but at no time was the road stopped from this cause." After referring to some unfavourable points in the construction, he says, "with proper construction I believe the Love system would be a great success. . . . We have demonstrated that we could operate five times the number of cars that we are now doing with practically the same expense. . . . Your claim that your system is free from danger to the public is fully sustained."

THE ELECTRIC LIGHTING CONDUIT IN THE CHICAGO EXHIBITION GROUNDS.

To provide for carrying the immense number of wires from the central-power station in the Machinery Hall in the Exhibition grounds to the Electrical and other Buildings where current is to be used, an immense conduit 6½ feet square has, says the *Electrical World*, been built directly under the Machinery Hall. This conduit extends across the grounds only very slightly below the surface to the Electrical Building, from which branches are carried to other sections of the grounds. The accompanying illustration gives a good idea of the construction of this conduit. It has a timbered framework, and is completely enclosed by thick planking spiked to the framework on the outside. The studding, a part of which is shown at the left of the illustration, is composed of 3in. by 6in. timbers, set about 9in. or 10in. apart. The arms for carrying the wires are attached to the cribwork by means of cast iron socket frames, which are attached by heavy lag screws to the studding, as shown in the illustration. These iron frames are made with a number of deep sockets, into which arms are driven, and which afford a broad and ample bearing surface for their support. The arms are driven back against the planking on the outside of the cribwork. Over the inside of the studding is placed a covering of latticework, shown in the illustration, to which is attached an artificial



Chicago Exhibition Electric Subway.

Digitized by Google

plaster board, so that the framework of the conduit is entirely sealed. On the cross arms are carried ordinary insulators, to which the cables are attached in the usual way. Arms are carried on both sides of the conduit, and are just long enough to leave space in the centre for a man to walk through conveniently whenever it is necessary to inspect the wires or to make any repairs. The floor of the conduit is slightly V-shaped to carry off any water which may get into the conduit. The illustration shows the entrance to the conduit directly under the power house. The whole construction is substantial, inexpensive, and permits of ready access to the wires which are carried through the subway.

A LIFE AND EFFICIENCY TEST OF INCANDESCENT LAMPS.*

BY PROF. B. F. THOMAS AND MESSRS. P. MARTIN AND R. H. HASSLER.

There is a great divergence between the published claims of lamp makers and the statements of the experience of station managers. Makers generally say that they will guarantee 600 hours' life for their lamps, and from 10 to 14 or more lamps per horse-power; but some station managers insist that they do not get an average of 400 hours' life. Considering it of prime importance for our object that the lamps tested should be of the same character as those usually sold to consumers, we bought some lamps of regular dealers, as in the usual course of business, and obtained others from lots supplied for central-station use. Lamps of the following makes were obtained, no attempt being made to get lamps of any given efficiency of any make:—A. B. C., Beacon, Columbia, Economic, Packard, Pennsylvania, Standard, Thomson-Houston, Edison, Perkins, Sawyer-Man, and Steuben. In ordering (through persons purchasing for us in Chicago and New York) we called for 10 110-volt lamps of 16 c.p. in each case. Ten Sunbeam lamps were divided into two lots of five each, evidently supplied as a sample lot, and were excluded. We could not get others of that make in time to enter the test. There were in all 127 lamps, labelled 110 volts and 16 c.p., of 12 well-known makes.

Current was supplied to the lamps by a 200-light Thomson-Houston dynamo, of the spherical armature type, which proved to be an excellent machine for the purpose. A special device was used to keep the potential at the centre of distribution constant, and it kept the potential difference at the centre at 110 volts, within a limit of three-quarters of a volt either way. For the candle-power measurements a 2-c.p. Methven screen was used, the gas being passed through a Methven carbureter containing pentane. Its constant was checked by standard candles. Three 32-c.p. Edison lamps were used as working standards.

Before the duration test began, the mean horizontal candle-power of each lamp was determined in the usual way, and the ratio of this mean to the candle-power found when the plane of the ends of the filament was perpendicular to the photometer bar was found, and used as the distribution factor. All results are expressed in terms of mean horizontal candle-power. The duration test was begun on March 17th, and it was necessary to run night and day, Sundays excepted, until the night of May 14th to complete 1,200 hours. The run began with 77 lamps on the rack. The remaining 50 lamps were received later, and placed on the rack with the others 187 hours after the start.

The object we had in view in undertaking the test was to determine the character of the incandescent lamp as a commercial product, not as a scientific instrument. The number of lamps of each make taken was, of course, too small to base a fair judgment on as to the absolute or relative merit of the lamps generally sold by the makers. For that purpose some hundreds of lamps of each make, taken from different lots, would have to be tested, which it was of course impossible for us to do. For this reason we have considered it unfair to the several makers concerned to give their names in connection with the results on their lamps, but have instead designated each make by a letter, and each lamp by a number. We believe, however, that the average of the results of all makes may be taken to represent fairly well the character of the average commercial lamp.

The results of the test are given in the tables on following page, the values given being in each case the average for a given make of lamp. Table I. gives in the second column the average value of the distribution factors found for the 10 lamps of make "A," and the average value of the mean horizontal candle powers for those lamps at intervals after the beginning of the duration test, expressed in hours by numbers in the first column. The third column gives corresponding values for the lamps of make "B," and so on. Table I. includes the lamps started March 17th. Table II. contains similar data for the lamps started 187 hours later.

Table III. gives the mean percentage of original candle power for each make at times given in the first column.

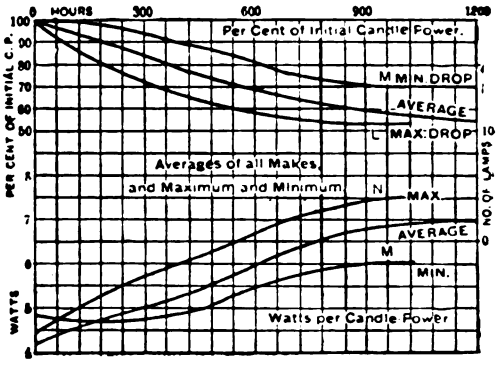
Table IV. gives the average watts per mean horizontal candle power for each make, at times given in the first column.

Thirty-one lamps in all were broken, distributed as follows: All of the C's (10), 2 D's, 8 E's, 2 K's, 4 L's, 1 M and 2 N's. All the lamps of A, B, F, G and O makes survived, the O's for 1,013 hours, the others for 1,200. The average life of the C's was 336 hours.

The plate below gives two sets of curves. One set gives the curve of general average of percentage of initial candle power with respect to time, derived from the averages of the several makes, and beside it the curve of the make which showed highest percentage throughout, marked min. drop, make M, and also the curve showing lowest percentage, marked max. drop, make L. The other set shows the general average of watts per candle power, and also the curves of the two makes showing the maximum (make N) and minimum (make M).

Examining the results first for candle-power, we find the value 14·5 as the average of all the lamps tested at the time the current was first turned on them. Of the 13 separate lots, six only show an initial candle power of 16 candles (neglecting tenths), though one make which started at below 15 rises above 16 within the first 100 hours. The lowest initial candle-power is found for make M. Makes G, K and O start at 17 candles, the highest figure reached at the start.

Looking at the curve which gives the average percentage of initial candle-power, we find that the lamps on the average grow dim at a steady rate, falling off to 90 per cent. in about 200 hours, to 68 per cent. in 600 hours, and end at 1,200 hours with a little less than 55 per cent. Deferring the consideration of the C lamps, the M lamps sustain their power best, losing only about 6 per cent. in the first 300 hours, and ending a little under 70 per cent. of their initial candle-power. The L lamps drop rapidly on the start, losing 30 per cent. in the first 300 hours and ending at 54 per cent. The E's and the O's drop to 47 per cent. at the close, but sustain themselves better than the L's in the earlier part of the run.



With respect to efficiency, using the term in its ordinary signification, as measured by watts per candle-power (though in this sense the reciprocal is the proper measure). The curves show an average initial value of 4·2, rising to 5·0 at 300 hours, 5·9 at 600 hours, 6·8 at 900 hours, and 7·0 at the end. The M lamps again have the best place, starting high but ending low, at six watts per candle-power.

But what shall we say of the results as bearing on the question of the life of the lamp? The answer depends on what we shall define the life of a lamp to be. Is a lamp alive as long as current will go through it? Adopting this view, our test shows 96 out of 127 lamps decidedly alive at the end of an average of 1,120, and the levelling of the average curves promises a considerable extension of their existence; 31 only have proved their mortality, and several of them lived to a good old age. The C's, poor things, all died young. If we set the time of decease at the time when the lamp gives 50 per cent. of its initial candle-power, as some claim, the lamps tested have passed 1,000 hours on the average, and certain makes have passed 1,200. If life be defined still with reference to percentage of initial candle-power, but the limit be placed at 75 per cent., some individuals are still alive, but on the average, all died at 450 hours; 80 per cent. as limit cuts them off at 330 hours, and 90 per cent. at 180.

But there is yet another way of defining the life of a lamp. The one who ultimately pays for the lamp is the one whose premises are lighted by it, and the thing he is supposed to pay for is light. For him, the lamp is dead when it ceases to give a certain candle-power, without reference to what its candle-power was when it was new. His premises, let us suppose, are properly lighted by a

* Abstract of a Paper read at the general meeting of the American Institute of Electrical Engineers, Chicago, June 6, 7, and 8, 1892.

Digitized by Google

certain number of new lamps, which actually give 16 c.p. But when their light drops to 14 (12½ per cent.), he is no longer satisfied (and he ought not to be). For him the average lamp lasts about 240 hours. But if he is at liberty to choose the make of lamp, without reference to its efficiency, he will probably call for lamps of the G make, and get 400 hours' service from them. If, however, he can induce the maker of the M lamp to make a lamp giving 16 c.p. when new, and having the same characteristics as those we tested, he will choose M's, and get 500 hours' life. And that is the best that can be done for him, so far as this test shows. He would not have B's, L's, or M's, as at present made at all, because they do not give 14 c.p. when new, and if the station manager puts in F's or N's he would order them out in less than a week. The state of things revealed by this test, as to the actual candle-power of new lamps, is certainly not what it ought to be.

At the conclusion of the life test we dismounted all the lamps and placed them on a large table covered with clean drawing paper and uniformly lighted. The several lots were carefully examined with reference to blackening, the lot which was blackened the most being graded 100, and the other lots graded as closely as we could judge by comparison with the blackest lot and with one another. The grades are as follows: 10, 12½, 25, 28, 30, 32, 35, 42, 45, 50, 75, and 100 per cent. of the blackening of the blackest lot. When the sorting and grading were satisfactorily completed, and the letters on the lamp bases examined, it was remarked that *the two lots which were least blackened were of the makes which are advertised as exhausted by mechanical pumps.* That they should both be so much alike in blackening, and both only one-half as much blackened as the least blackened of the mercurially exhausted lamps, is, to say the least, worthy of notice. It is, of course, not established that the observed freedom from blackening is due to the absence of mercury vapour in the lamps, as the makers claim, but if investigation should establish the claim the mercury pump will probably become once more a laboratory instrument.

So far as the lamps tested may be considered to fairly represent it, we draw from the test the following conclusions concerning the average 16 c.p., 110 volt, incandescent lamp:—

1. The mean horizontal candle power of the lamp as defined is only 14·5 when new instead of 16 as labelled.

2. The candle-power of the lamp diminishes at a fairly uniform rate as it is burned, the rate of decrease being roughly 10 per cent. of the initial candle-power for each 200 hours burned.

3. The lamp makers' claim that the lamp will burn for 600 hours before breaking, is more than established, 96 out of 127 lamps being unbroken at the end of over 1,100 hours.

4. Defining the life of a lamp to be the number of hours it will burn before it will fall from 16 c.p. to 14, we find the life of lamps in all respects like those tested, but so made as to give an initial candle-power of 16, is 240 hours.

5. The initial efficiency of the lamp is 4·2 watts per candle power. At 600 hours it is 5·9 watts, and 1,200 hours 7 watts. The average efficiency during the first 600 hours is 5·04 watts.

6. There is considerable difference in the rating of lamps by different makers, who nominally furnish the same article, the average initial candle-powers of the several lots ranging from 12·5 to 17·0. There is also considerable difference in the uniformity of the product of different makers.

The above conclusions properly complete this Paper, so far as the purpose of which the test was undertaken is concerned. Some interesting points in the relative performances of different lamps may perhaps be alluded to in addition, since they cannot affect the makers.

The most interesting result arises from a comparision of the lamps L and M. The L's have the highest initial efficiency (3·8), and the M's the lowest (4·8), excluding, of course, the C's, which cannot be classed with good lamps, but after 250 hours' burning the efficiencies are the same (4·75). At the start the L's are furnishing light at the least cost, but after 250 hours the M's have the advantage in this respect. If we suppose both makes to be used for 700 hours, the average efficiency is the same for both. But at this time the M's are giving 75 per cent. of their initial candle-power, while the L's are giving only 55 per cent. For the consumer the M lamp is the better of the two, since the lighting of premises will be more uniform throughout the 700 hours of use supposed, and the cost of current for a given aggregate of candle-power hours is no greater than with the L's. If the time of use of the lamps be, say, 400 hours, the choice is not so evident, and will depend on whether the slight difference in cost (watt hours) is of greater or less importance than constancy of candle-power of the lamps.

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny.

Editorial, Publishing, and Printing Offices

SALISBURY COURT, FLEET ST., LONDON, E.C.

Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.* "THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Old Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

SMALL ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications, dealing with Electrical and kindred subjects, can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" *Series of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.*

"THE ELECTRICIAN" *Series at present consists of—*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.

VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free.

VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post-free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. **Price 2s., post free.**

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING. By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d., post free.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. [*Nearly ready.*

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. [*Nearly ready.*

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

DRUM ARMATURE WINDING, AND COMMUTATORS: (1.) In Theory and Practice. By F. M. WEYMOUTH. [*Nearly ready.*

ELECTRICITY AS A MOTIVE POWER. By A. T. SNELL. [*In preparation.*

Now Ready, in Two Volumes. Prospectuses Free.

"THE ELECTRICIAN" PRIMERS. *Fully Illustrated.*

Price: Stout paper covers, 2s., post free, 2s. 2d. each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

FULL CATALOGUE POST FREE ON APPLICATION.

All kinds of Technical and General Printing and Publishing undertaken by "THE ELECTRICIAN" *Company. Estimates free.*

SPECIAL NOTICE.

With the issue of "THE ELECTRICIAN" for August 5th will be published a fine STEEL-PLATE PORTRAIT of LORD RAYLEIGH, M.A., D.C.L., LL.D., F.R.A.S., F.R.G.S., &c., with Autograph.

Subscribers to "The Electrician" should receive this Supplement Gratis, and complaints of non-receipt should be promptly addressed to the Publisher of "The Electrician."

NOW READY.

Volume XXVIII. of "THE ELECTRICIAN," price 12/6; post free, 13/6; abroad carriage extra.

ALSO NOW READY.

Cases for binding Volume XXVIII., price 2/0, post free, 2/3.

COMPETITION.

Competition is regarded as a form of industrial suicide by one man and as the very salt of commercial enterprise by another. It must be admitted that, when a large proportion of the exertions of a firm or of an individual is expended in opposing, frustrating, or wastefully supplementing the work of another, there is waste indeed, and waste not only of time and money, but of good work which might better have been spent in some other direction. But while commerce and manufactures could doubtless continue to meet existing demands without competition, all real progress is essentially connected with this principle; and any interference with it will not only deaden the originality of the producer, but must limit the choice of the consumer. Most contractors who have tendered for shiplighting sets for the Admiralty have complained of the cutting of prices; but perhaps nothing else has done more to develop and to improve the continuous-current dynamo in this country than the stringent conditions as to weight, size, and heating which have been laid down in the Admiralty specifications. Before there was any such competition, the Admiralty accepted and used those extraordinary and elephantine machines which were called B Grammes; and it is difficult to conceive by what else than the spirit of

Digitized by Google

trade emulation improvements could have been achieved. Neither the maker nor the buyer has any idea of the possibilities which are within easy reach unless this powerful incentive to progress is felt. There has been much less competition in the high-speed engines used for shiplighting. The Willans has been most successful, but the Admiralty engineers have been opposed to the closed sides; and although engines, of which one was shown at the Crystal Palace, have been built to meet this doubtfully founded objection, they have taken the matter in their own hands and have built an engine for themselves at Portsmouth Dockyard. It is to be hoped that this will be used as a pattern for the guidance of other makers, rather than as a precedent for the construction of engines for shiplighting by dockyard labour, for the chance of further improvement would then be remote. We probably should not yet have had sixpenny telegrams in this century had it not been for very shame that other nations were leaving us behind; and but for the same incentive we should still have been obliged to send letters for India and China in large quantities to France, whence they could be posted for twopence halfpenny instead of fivepence; and even now the only economical way of posting samples to English towns is to send them first to Belgium. Without the prospect of wholesome competition it would be too much to expect our glow lamps to be even what they are, and we shall not be surprised to find some marked improvements before two or three years have elapsed.

Competition conduces perhaps to development in quality with less disagreeable results than where price is principally affected. In the former case, it is true that the producer who is only second best in the race is compelled to modify his work, perhaps to replace his plant, by improved machinery, having by over confidence found himself encumbered with obsolete stock. Where there is little choice in quality, the fight for price seems sometimes to support the pessimistic idea of industrial suicide to which we have alluded. When prices are cut so much that capital cannot earn four or five per cent., it is quite time that that better part of valour, discretion, should be used; when dividends are declared in shillings per share, it often means that too much capital has been attracted, or, at least, that it has been improperly spent.

COMMUTATORS.—III.

BY F. M. WEYMOUTH.

(*Continued from page 309.*)

Now as to the washers and heads, it will be noted that in Fig. 5 (see p. 309 of our last issue) there is one of the former at each end, on account of the flat head. A point, however, to which attention may be drawn is the angle with the axis under the head and washer, as at *m* and *n* Fig. 3 (see p. 309 of our last issue), assumed in different designs. This, as will be seen further in subsequent sketches, varies from about 60° and 50°, to 45°, 30° and even less. A great difference thus exists. The principal point to be attained, however, beyond holding the segments securely against the centrifugal force tending to make them fly off, is to hold them so firmly together, considering the large number of parts forming the whole, that they shall not easily be put out of truth after leaving the lathe, by any accidental blow or jar. With the larger angle, the best effect of course is to hold the segments tightly between the washer and head; while the smaller angles have a best effect in holding the segments in toward the axis. It has to be considered, however, that insulating materials have not the same density and solidity as metals. They, moreover, vary in nature, and, as has already been pointed out, fibre is apt to absorb moisture and swell thereby, and to shrink again when dry and hot. Now this shrinkage would naturally have more effect in loosening the bars diametrically with the large angles than the small. Thus a small angle with the axis might seem the best with fibre. But a substance less liable to shrink, such as mica, may be preferable for large angles. Conversely also, in consideration of its laminæ being in planes normal to the axis of the shaft, a large angle would be better for the mica, when so used. With a small angle and assuming the possibility of there being any *give* in the insulation between the bars, and assuming further that these are tightly fitted on the cylindrical body of the sleeve, with hard insulation between, then on the nut being tightened up, and the slope of the washer having its best effect diametrically inwards, there would be a tendency for the ends of the bars within the washer to become jambed against the sleeve, the slope of the washer in a manner acting as a wedge. The result of this would thus be, that the segments dragging on the sleeve would not be driven home so tight under the head as under the washer. In Fig. 5, where the angle is very small indeed, any possibility of this eventuality is met by the fact that the washers at each end lie flat against the nut and head respectively, and also against the bar ends; and thus the bars are driven directly by the nut. There does not seem much allowance here, however, for any give of the insulation enclosed between the washer and the projecting heels or snugs of the segments. A practical point is to allow a thickness of sleeve where the nut rides for a sufficiently large thread; and a length parallel with the axis, such that the nut may not be too thin: thus tight screwing up may be effected without the thread stripping, or the nut bursting, which is of course a matter of primary importance in securing the solidity of the whole mass. This nut, it should be mentioned, requires to be locked to prevent possible slacking back. One method is to put radial screws through it, generally three, with their points taking into the sleeve. Another method is to put one or more screws parallel with the shaft through the nut, with their points taking into the washer, as shown in Fig. 13.

But now we may turn our attention to commutators of the second kind in our classification. We find these exemplified in Figs. 7 to 10. Of these, Fig. 7 is a Kennedy design; Fig. 8 an example from a "Westminster" dynamo by Messrs. Latimer Clark, Muirhead, and Co.; Fig. 9 a Gülcher; and Fig. 10 an early type of Kapp commutator. Here, as was intimated, a special object has been to secure a short total length in proportion to the length of brush contact surface. The difference between these and the first four is at once apparent, in that they are undercut at the ends, and the washer and mushroom head more or less let into the ends of the segments. This is especially the case with Figs. 7 and 8; while with the former in particular the total length scarcely exceeds that of the segments. A further difference, however, will be seen, in that while the segments of the first four were all bedded on the sleeve with insulation between, in these latter there is no insulating material here, an air space between being left instead. Moreover, whereas the washers and heads of the former had only one slope, tending to force the segments inwards, in these latter, excluding Fig. 8, there are two slopes. Thus the effect of tightening the nut is to maintain the segments at a constant diameter or pitch, instead of only forcing them inwards. This forms an essential difference in construction. The angles of the reverse slopes are 45° with the axis of the shaft. Now in Fig. 8 we find this peculiarity that air spaces are left, lettered *l l*, between the inner side of the undercut, and the outer periphery of the insulation; while at the same time there is no bedding on the sleeve, and the washer and head have only one slope. Thus the bars are all simply pressed inwards by tightening the nut, and held together like the voussoirs of a circular arch or culvert; the case would be analogous in Figs. 3 to 6 were the interior insulation round the sleeve omitted or be but loosely fitted or packed in. If, however, returning to Fig. 8, the spaces *l l* were filled up solid, then the segments here also would be maintained at one set diameter or pitch, as in the case of Figs. 7, 9, and 10. Assuming, however, the single slope, without there being any direct support for the bars radially from the

Digitized by Google

centre, then, especially when the commutator is divided into a large number of parts, the taper of each segment on its cross section is so slight that an accidental blow on the outside, on any one or two of them, might drive them in, in spite of the tightness of the nut; thus the whole would be put out of truth, necessitating a return to the lathe. Hence a direct support both inwards and outwards would appear preferable, either by means of the single slope under the head and washer, and bedding on the sleeve, or else by double slopes on washer and head, as in Figs. 7, 9, and 10.

Now in these four designs, Figs. 7 and 8 especially, it will be seen that the brushes cannot wear right through, as they were open to do in Figs. 3 to 6, for they would reach the washer and insulating ring before doing so. They all have a clear shoulder, as at *i*, Fig. 4. It might appear in reference to Figs. 7 and 8 that on much wear taking place the sections of the segments at *r* would become so reduced as to choke the current flowing to and from the lug. But as so little wear is allowed at all, renewals would be needed before much trouble in this direction could arise, at least, in the case of Fig. 7. Excessive wear may, of course, lead to difficulties here, as elsewhere. In the other designs the undercut is not nearly so great. It may be observed that there was a slight undercut at the lug end in Fig. 6.

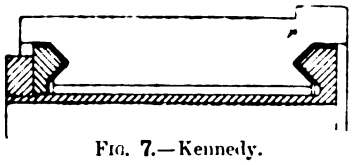

Fig. 7.—Kennedy.

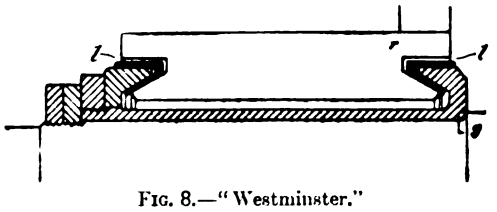

Fig. 8.—"Westminster."

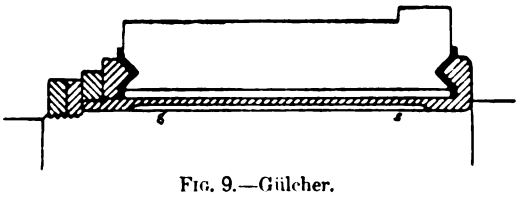

Fig. 9.—Gülcher.

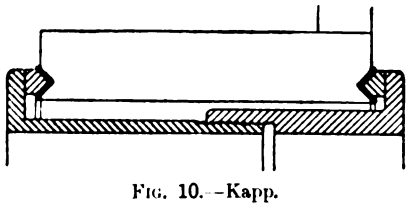

Fig. 10.—Kapp.

Regarding the matter now, however, from the point of view of prime cost, we find these latter four examples compare favourably with the former. Thus a slight gain accrues at once from the shorter sleeves. But from the fact that there is no insulation between the bars and the sleeve, and provided the air space thus left is not less than, say, $\frac{3}{16}$in., there is no necessity either to bore the interior of the segments or to turn the outer cylindrical surface of the sleeve; and so machining is saved. In Fig. 9 a further saving in this same direction is effected by chambering the interior cylindrical surface, lettered *s s*, thus leaving only the ends to bore smooth to fit the shaft, while the chambered portion need have only a roughing cut taken off it, if any. Moreover, as the length of the segments themselves in the latter four does not exceed what is required for the brushes and lugs, whereas in all the other designs we illustrate there are projections at both ends beyond these limits, metal is saved in this respect. Economy is also effected, of course, in insulation.

Now, a distinctive feature in Fig. 10 is that nuts are eschewed, and two sleeves are used, the one screwing into the other, as shown. As in Fig. 5, however, it has two washers, one at each end, and both from the same pattern. We may note that these have a characteristic which they hold in common with the washers in Figs. 5 and 6. For they simply ride on the projecting heels of the segments, and have no efficacy themselves in maintaining the truth of the commutator beyond forcing the segments on to the interior insulation. In the other designs before us the washers are bored to fit the sleeve, and so are centred on it; and they are thus the better adapted to assist in maintaining the truth of the commutator. A further distinctive feature in Fig. 10 is that they are not centred on anything, and entire dependence for maintenance of truth is apparently placed on the friction of the grip between the sleeve heads.

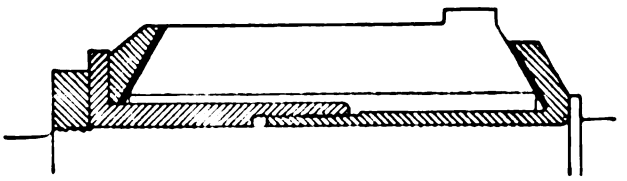

Fig. 11.—Kapp.

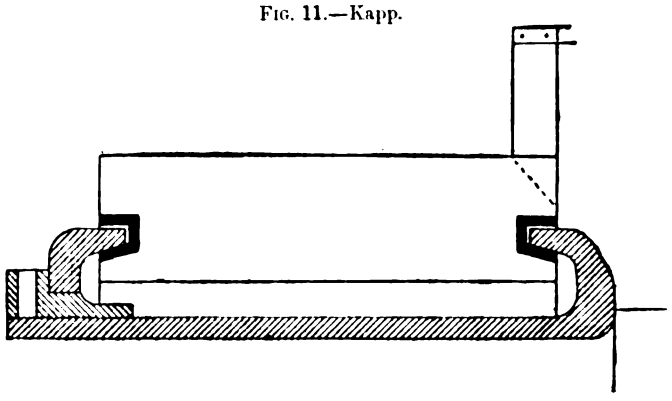

Fig. 11A.—Kapp.

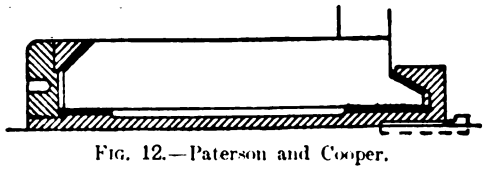

Fig. 12.—Paterson and Cooper.

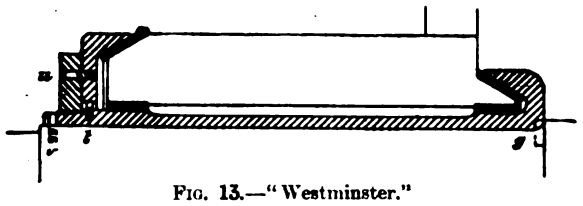

Fig. 13.—"Westminster."

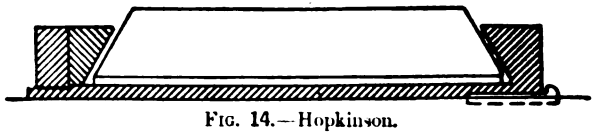

Fig. 14.—Hopkinson.

An advantage, however, in connection with these latter four designs is that for larger diameters of commutator, while assuming the same diameter of shaft, it is only necessary to increase the diameters of the washers and nuts, simply leaving a larger air space between the segments and the bush. For very large diameters the bush may be double, being composed of an inner cylinder riding on the shaft, and an outer cylinder carrying the segments, united by radial ribs to the inner one. By this arrangement passage for ventilation is afforded by the space between the cylinders.

We now come to four more designs, Figs. 11 to 14. Of these the first two, it should be stated, we borrow from Prof. Silvanus P. Thompson's "Dynamo Electric Machinery." Fig. 11 is another design by Mr. Gisbert Kapp, and Fig. 12 one by Messrs. Paterson and Cooper. Fig. 13 is another "Westminster" design; and Fig. 14 is a design adopted by Dr. Hopkinson, though with this latter we are not able to show any insulation. Fig. 11 will be seen to be similar to Fig. 10 in having a double sleeve: otherwise it is totally

Digitized by Google

unlike. It is, however, similar to Fig. 14 in simplicity of end slope, and in having very large angles. Fig. 11A represents Mr. Kapp's latest form of commutator, which we borrow from the very fine collection of plates at the end of the fourth edition of Prof. Thompson's book above referred to. It will be observed that the double sleeves are abolished, only a very fragmentary idea of a second sleeve being represented by a prolongation of the nut. Comparing with Fig. 8, it will be observed that the gaps there lettered *l* are here inside the insulating cones, instead of outside. But this apparently small transposition of the gap is not without effect. It will be seen that it makes all the difference between the circular arch principle of support for the segments, already alluded to, and a solid central bedding. For with the gap inside the insulation, as shown in Fig. 11A, the segments are directly supported by the cones at either end, and so cannot fall inwards toward the centre, and are, in fact, held at a certain rigid pitch or diameter, in the same manner as with Figs. 7 and 9. The horizontal and vertical gap, combined with the small angle, at the same time permits of the flanges of the mushroom head and washer being forced up so as to give the cones a thoroughly tight grip centrally; though the lasting efficacy of this may depend on the insulating material used, in conjunction with atmospheric and other external conditions. There is no insulating substance between the segments and the sleeve; and the effect of the very small angle under the mushroom-shaped nut and head being to draw the segments hard in towards the axis, there is nothing approaching a drag on the sleeve tending to prevent the segment ends going home equally tight under the head and under the nut. The washer rides on a shoulder of the nut, and so is centred on it. More economy of metal is attained in the head than in some other designs, and the outer slope and rounded angles of this assist the passage of air from within the armature. It may be noted further how that, in accordance with previous remarks, owing to the adoption of an air space for insulation between the segments and the sleeve, and to the supporting of the segments at the ends only, a large diameter may be, and is, reached by simply increasing the diameter of the washer and head. The sleeve, nut, and washer are of gunmetal.

Figs. 12 and 13 will be seen to have similar segments, and both differ from the remainder in that they have insulation under the ends of the segments only. They thus effect a compromise in this respect between the first four designs and the second four we have illustrated. Bedding on the sleeve is secured without the expense of carrying this the whole length of the segments, and so saving in both machinery and insulation is effected. In Fig. 12 a small washer of triangular section is used, which rides, however, on a shoulder on the nut, and so is centred. In Fig. 13 the washer rides on the sleeve, and is prevented from turning by a pin let into the sleeve, as shown at *t*. The object of this is two-fold, inasmuch as it prevents any possibility of slewing the segments on tightening the nut; and also it gives security for locking the nut by means of the screw *u* put through both parallel with the shaft as shown. Another simple method for securing the same ends is to cast a snug on the inner periphery of the washer, in such a manner as not to interfere with its being turned in the lathe, which shall engage between snugs or in a slot in the sleeve. For the evil of slewing the segments, caused by the washer going round with the nut (when not prevented), and taking the ends of the segments with it, is not an imaginary one; though many makers rely on the tight clamping of all the parts together during the process of tightening up the nut, for its prevention. A further distinctive feature about Fig. 13 is that it is put on the shaft without being held there by a nut or nuts at the end. A sufficiently stout steel screw is put in at the end of the sleeve projecting beyond the nut, as shown at *v*, experience, so far as we are aware, justifying this as quite enough. For as there is no conceivable force, at least such as could be anticipated, apart from mere vibration, with a tendency to separate the commutator from the armature, there seems no reason why the simple screw should not be sufficient. This method is, however, not peculiar to the one type we illustrate.

(To be concluded.)

RECENT DEVELOPMENTS IN ELECTRIC ARC WELDING.

BY P. I. UNWIN.

In the arc process of electric welding under the Benardos patents three separate and distinct methods are in daily use. Between these there is a vital difference, and much difficulty and confusion have arisen from the want of distinction between the three. The first method is welding proper, in which the wrought iron or steel to be united is raised only to the welding temperature, and a perfectly fibrous weld is thereby obtained, which is as strong as the original material, and may be stronger if sufficient work, either hammering or pressure, be put upon the weld. No reinforcement of the weld is used in this case.

The second method is called a "built weld," by which small pieces of metal are melted into the joints and hammered in. The melting, of course, destroys the fibre of the metal, but this is partially restored by the work put upon it. The joint in this case will probably be part fibrous and part crystalline on fracture, but any weakness owing to the percentage of crystalline metal will be largely allowed for, in the additional thickness which this weld possesses. It has been found advisable, after the trial of many materials for reinforcing a built electric weld, to use a special grade of very mild low carbon steel. In the following sketch (Fig. 1) at A and at B may be seen examples of these two methods of welding: A illustrates a built weld, B illustrates a weld proper.

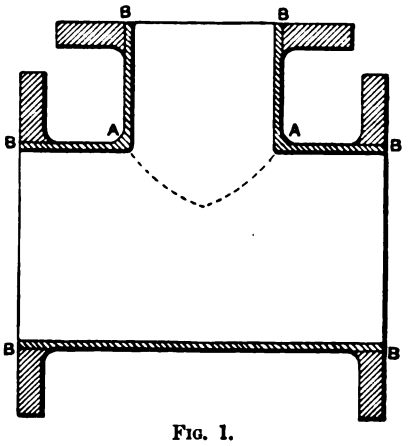

Fig. 1.

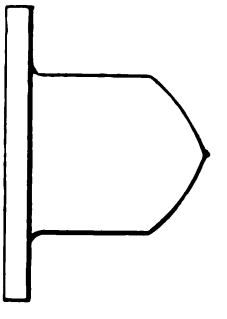

Fig. 2.

Tee Piece for Marine Steam Pipe.

The third method is not at all suitable for the welding of wrought iron and steel. It is used chiefly in repairing *castings*. It consists in fusing pieces of metal into the weld—or defective place in the casting—until the metal is a molten mass locally. In the case of cast steel the hammer may be applied to produce a smooth surface, when the metal has partially cooled; but in the case of cast iron the whole casting must be kept black hot during this process of cooling. In welding wrought iron and steel it is of vital importance that the arc should be maintained at least 2in. long or more, and should be kept continually and rapidly moving over the surface of the metal to be heated.

Let us take for example the case of a steel flanged "tee" for a marine steam-pipe line, say 8in. diameter, having a 6in. flanged outlet. This embodies the first two methods of welding, and also utilises the arc, not for the purpose of uniting, but for separating the metals. A piece of tube, 8in. internal diameter and $\frac{5}{16}$in. thick, is taken, and a circular hole, 6in. diameter, cut by means of the arc. This is effected with a powerful short arc, held stationary, and close to the metal, through which it quickly cuts a groove about $\frac{1}{4}$in. wide; a circular hole about 6$\frac{1}{2}$in. diameter is thus made in the tube. The inner end of the outlet is then shaped by the same method, thus (Fig. 2), and the two are then placed together, and lightly tacked to keep them in position during the welding. Pieces of steel are now welded all round the joint, being fused in place, and then hammered to shape while cooling, forming thus a strong fillet all round the joint.

Digitized by Google

The current required for this process is about 150 amperes and 65 volts at the arc. The outlet now being welded, the flanges are next shrunk on, each being about 1in. thick, and 14in. diameter. The operation of welding these flanges comes under the first category of welds, and is most speedily effected by means of two arcs working in parallel on the weld, one within, and the other on the flange, and outside the tube. About 4in. will be heated at a time in this way, using 300 amperes in each arc.

Many people have been surprised by the large area of metal thus heated at one time; but it should be remembered that intense local heating raises the metal beyond the welding temperature, and at best produces merely a soldered joint, the plastic stage, when the metal is weldable, being passed too rapidly for it to be taken advantage of. Having now its three flanges welded on, the tee is tested hydraulically to 800lb. per square inch. It is found that if the test be carried to the destructive limit 1,700lb. per square inch will be sustained before fracture, which will probably take place in the form of a slight crack in the throat of the fitting at A. It will be seen, therefore, that if a fitting is used for steam at a pressure of 170lb., a factor of safety of 10 is thus allowed for, which is amply sufficient, in the opinion of "Lloyd's Shipping Register." Every fitting when complete is carefully annealed, taking 24 hours to cool, thus removing the possibility of any trouble arising from unequal strains caused by local heating. Finally, the flanges are turned all over, back and front, and drilled for the bolt holes.

Marine engineers, who have a large experience of the use of copper pipes and fittings with brazed flanges, will be able to judge whether steel pipes and fittings are not superior to copper, which is now so generally acknowledged to be treacherous at the high pressures of steam in use at the present time.

THE AYRTON-MATHER-D'ARSONVAL GALVANOMETER.

In the Paper on Galvanometers,* by Messrs. Ayrton, Mather, and Sumpner, which was read before the Physical Society on January 17, 1890, it was recommended that the suspended coil of a d'Arsonval galvanometer should be long and narrow, that there should be no stationary iron core, and that the poles of the magnet should be very close together; and on March 21, 1890, in a Paper, by Mr. Mather,† upon the Shape of Movable Coils used in Electrical Measuring Instruments, the subject is more fully dealt with. It was shown in the latter Paper that in ordinary commercial instruments it is important that the period of oscillation should not be inconveniently long, and that the power consumed by the instrument should be as small as possible. Then, since for a constant period the controlling moment at unit angle must be proportional to the moment of inertia of the moving part, the problem resolves itself into finding the shape of the section, such that the total deflecting moment for a given total moment of inertia is a maximum. The most efficient section of the suspended coil was found to consist of two circles, touching one another at the vertical axis of suspension. Another way of treating the problem resolved itself into finding the shape and position of an area having a given moment of inertia about a point in its plane, such that the moment of the area about a coplanar line through the point is a maximum. This gave an identical result. In the Ayrton and Mather-d'Arsonval galvanometer, made by Mr. Paul, and exhibited at a recent meeting of the Physical Society, a narrow coil is enclosed in a silver tube, which serves the double purpose of damping the motion and as a case or mounting for the coil, allowing it to be handled and clamped for travelling, without fear of injury. The mirror is attached to the silver tube by a light three-armed clip, thus avoiding the difficulties of cement. Fig. 1 shows the tube and mirror, full size. Part of the tube is broken away to show the coil, and the connection of the end through an insulating collar. Fig. 2 shows the outer brass tube half-size. The coil tube is hung within it by a flattened phosphor-bronze wire, and the lower connection is made by a spiral of phosphor-bronze. A mirror-box is provided with a sliding glass plate. The clamping arrangement is well devised, and consists of a button sliding in a slotted spring. When the button is at the top of the slot, as shown in Fig. 2, it

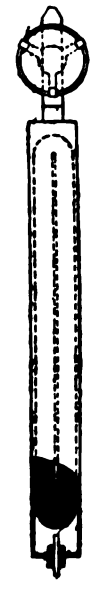

Fig. 1.—Coil Tube and Mirror, full size.

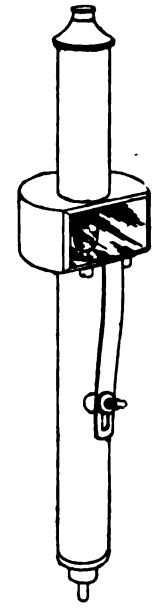

Fig. 2.—Outer Brass Tube, half size.

is opposite a hole in the outer brass tube, and by the pressure of the spring holds the silver tube without putting any longitudinal strain on the suspension. To release the clamp the button is drawn forwards and pushed down in the slot. The outer tube, with its mirror-box and torsion head, is self-contained, and the act of sliding it into its position between the poles of the magnet makes the contacts. These tubes are interchangeable, and several coils of different windings can be kept ready, and slipped in place in a few seconds. The permanent magnets are of circular form

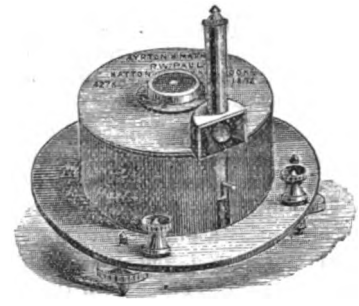

Fig. 3.

(Fig. 3), with a narrow gap between the poles. A circular level and insulated levelling screws are provided. The advantages of portability, dead-beatness, and quick swing are thus combined, without any sacrifice of sensibility.

FOREIGN ELECTRIC LIGHTING AT THE CHICAGO EXHIBITION.

The following extract from a report to the Royal Commission, made by the Secretary of the Commission (Sir Henry Wood), on his return from Chicago, will be read with interest:—

Electric Lighting.

I made inquiries as to the arrangements for electric lighting, and ascertained that a small amount both of arc and incandescent lighting is being retained for foreign exhibitors, and that if any English company desired to take this up on the terms which have already been published, they could do so. The main bulk of the electric lighting has been arranged for on a commercial basis with American firms. They have not yet got all

Digitized by Google

the power required for running dynamos, and would be glad if English exhibitors could send one or two 500-horse power engines for the purpose. These engines would be placed among the power plant, and the space allotted for the purpose adjacent to the Machinery Hall.

Such engines would have to be delivered free on the cars at Jackson Park. Foundations would be provided and the engines erected by the Executive. The cost of running would also be provided, including wages of engineer, who might, if preferred, be appointed by the exhibitors, but would be under the orders of the Executive. Engines on the same bed plate as dynamo would be quite acceptable. At the close of the Exhibition the engines would be dismantled and placed on the cars.

Special arrangements are to be made for the lighting of the Electricity Building. In this each foreign section can, if it chooses, light up its own space. It is proposed to allow exhibitors to furnish all the lighting plant as exhibits. Steam would be provided free, but no payment would be made. Exhibitors who require current or light, and who do not provide generators, would be charged a low rate. Mr. Hornsby, the Chief of the Electricity Department, could not say what the rate would be, but it would be about cost price. The motors and generators would be placed among the power plant above referred to. Exhibitors will be expected to lay their own cables in the conduits, do own wiring, provide lamps, &c. The generators, cables, &c., might be supplied by different exhibitors.

Exhibitors generating current would be allowed to use as much light as they pleased for themselves. In addition to the light thus supplied, the building will be lighted by arc lamps. For this light there is to be no charge.

THE PROPOSED INTERNATIONAL CONGRESS AT CHICAGO.

We have been favoured with the following copy of the official document emanating from the United States Legation in London announcing the intention to hold a series of International Congresses at Chicago next year, and inviting the cordial co-operation of Her Majesty's Government :—

Legation of the United States,
London, July 16, 1892.

My Lord,

I have the honour to acquaint your Lordship that the Department of State of the United States is in receipt of a letter from Mr. Charles C. Bonney, President of the World's Congress Auxiliary, in which it is stated that, in pursuance of the course indicated in the original announcement of the World's Congress Auxiliary, which was transmitted to your Lordship in my note of February 2, 1891, with the Act of Congress approved April 25, 1890, and the President's invitation of January 14th, 1891, extending to all foreign Governments a cordial invitation to participate in the World's Columbian Exposition, to be held in Chicago in 1893, the work of the World's Congress Auxiliary has been organised to the present date in sixteen Departments, and more than one hundred General Divisions in which Congresses are to be held.

The preliminary organisation of these Congresses are contained in the preliminary publications of the Auxiliary, copies of which are herewith transmitted, and the accompanying printed pamphlets amply disclose the plans, aims, objects, and purposes of the Congresses.

I am, therefore, instructed to say to your Lordship that it is especially desired by my Government that the largest practicable participation of foreign peoples and Governments in the whole series of these important Congresses may be secured, and that it is particularly requested that a convenient number of the most eminent representatives of the various departments of human progress be selected as delegates to attend the respective Congresses, by or under the direction of each of the foreign Governments, in addition to those who will come as the representatives of the leading institutions and societies of the different countries. Such a co-operation on the part of other Governments will, it is confidently believed, tend in the highest degree to promote, strengthen, and extend those fraternal relations and mutual benefits which may now justly be regarded as the supreme object of international intercourse, and as involving a higher civilisation and a broader human progress.

I have, therefore, the honour of communicating this supplementary invitation to Her Majesty's Government; and, in doing so, I venture to call your Lordship's attention to the brief intervening period, and to express the earnest hope that Her Majesty's Government will be disposed to give the necessary co-operation to ensure the adequate participation of Her Majesty's subjects in these interesting Congresses.

I am directed also to say that on receipt of the names of such delegates as may be selected to attend these several Congresses, suitable communications will be promptly forwarded to them.

I have the honour to be, with the highest consideration,
My Lord,
Your most obedient humble servant,
(Signed) R. LINCOLN.

The Most Honourable the Marquis of Salisbury, K.G.

The Schenectady Works.—According to a Dalziel cablegram the Edison works at Schenectady were totally destroyed by fire on Monday morning.

ELECTRICAL STANDARDS.

The following circular, signed by the Secretary, Mr. R. T. Glazebrook, has been issued to the members of the Electrical Standards Committee of the British Association.

A meeting of the Electrical Standards Committee of the British Association will be held at Edinburgh. It is expected that Dr. von Helmholtz, Dr. Lindeck of the Berlin Reichsanstalt and others interested in electrical measurements will be present. A discussion will take place with a view to securing an absolute uniformity in the Standards adopted in England and elsewhere.

The following points will be considered :—

1. The value of the B.A. unit in ohms.
2. The specific resistance of mercury in ohms.
3. Standardising by the electrolysis of silver.
4. The electromotive force of a Clark cell.
5. Report of the Committee for 1892.

It is proposed to take the report of the Committee in the Section on Tuesday, August 9th. The draft prepared by the Secretary is formal; but it is hoped that the discussion in the Committee may lead to some resolutions which will be included in the report. The report of the Electrical Standards Committee of the Board of Trade is printed in the B.A. Report for 1891. Further information as to the values of the units is given in the B.A. Report for 1890. The following summary may be of use.

1. *The Value of the Ohm.*

	Observer.	Date.	Method.	Value of B.A.U. in ohms.	Value of 100 cms. of mercury in B.A.U.	Value of ohm in cms. of mercury.
1	Lord Rayleigh ..	1882	Rotating coil..	·98651	·95412	106·24
2	Lord Rayleigh ..	1883	Lorenz method.....	·98677	—	106·21
3	G. Weidemann..	1884	Rotation thro' 180°	—	—	106·19
4	Mascart	1884	Induced current ...	·98611	·95374	106·33
5	Rowland.....	1887	Mean of several methods.....	·98644	·95349	106·32
6	Kohlrausch	1887	Damping of magnets	·98660	·95338	106·32
7	Glazebrook ..	1882 and 1888	Induced currents..	·98665	·95352	106·29
8	Wuilleumeier...	1890	—	·98686	·95355	106·27
8*	Duncan & Wilkes	1890	Lorenz	·98634	·95341	106·34
8†	Jones	1891	Lorenz	—	—	106·31
			Mean	·98653		
9	Strecker	1885	An absolute determination of resistance was not made. The value ·98656 has been used.	—	·95334	106·32
10	Hutchinson.....	1888		—	·95352	106·30
11	Salvioni	1890		—	·95332	106·33
12	Salvioni	—		—	·95354	106·30
			Mean	.....	·95354	106·28
13	H. F. Weber ...	1884	Induced current ...	Absolute measurements compared with German silver wire coils issued by Siemens or Strecker.		105·37
14	H. F. Weber ...	—	Rotating coil.....			106·16
15	Roiti	1884	Mean effect of induced current ...			105·89
16	Himstedt	1885	—			105·98
17	Dorn	1889	Damping of a magnet			106·24
18	Wild	1883	Damping of a magnet			106·03
19	Lorenz	1885	Lorenz method.....			105·93

The Board of Trade Committee recommended for adoption the values 0·9866 and 106·3.

The specific resistance of mercury in ohms is thus :—

$$0{\cdot}9407 \times 10^{-4}.$$

Also 1 Siemens Unit = 0·9407 ohm
= 0·9535 B.A.U.
1 ohm = 1·01358 B.A.U.

2. *The Electrolysis of Silver.*

The following values have been found for the mass of silver deposited from a solution of silver nitrate in one second by a current of 1 ampere :—

Mascart, *Jour. de Physique*, III. 1884 .....0·0011156
Rayleigh, *Phil. Trans.*, II. 1884 .....0·0011179
Kohlrausch, *Wied. Ann.*, XXVII., 1886 .....0·0011183
T. Gray, *Phil. Mag.*, XXII. 1886 .....about 0·001118
Potier et Pellat, *Jour. de Physique*, IX., 1890 ...0·0011192

Digitized by Google

Dr. Schuster has shown, *Proc.* R. S., Vol. L., 1892, that the amount of silver deposited when the voltameter is in a vacuum is about 0·04 per cent. greater than when it is in air.

3. *Clark's Cells.*

The following values have been found for the E.M.F. of a Clark's cell at 15° C. They have been reduced from those given in the original Papers on the supposition that 1 B.A.U. = ·9866 ohm, and that the mass of silver deposited per second per ampere is ·001118 grammes :—

Rayleigh, *Phil. Trans.*, II, 1884	.....	1·4345 volts
Kahle, *Zeitschrift für Instrumentenkünde*, 1892.		1·4341 ,,
Glazebrook and Skinner, *Proc.* R.S., LI., 1892.		1·4342 ,,

A comparison has been made between the standards of the Association and the Berlin standards through a Clark cell and a resistance coil belonging to Dr. Schuster. By the kindness of Dr. von Helmholtz the secretary hopes to have a direct comparison between the two sets of standards completed before the meeting.

LEGAL INTELLIGENCE.

Re the Bankruptcy of Joseph Slater Lewis.

At the Birmingham County Court on Monday the public examination of this bankrupt took place. He is described as of 10, The Avenue, Castle Hill, Ealing Dean, Middlesex, late of the National Telegraph Works, Wainwright-street, Aston. In the course of the examination some peculiar facts were elicited by the counsel for the creditors. It appeared that the bankrupt started in business 20 years ago as a coal merchant, and in 1885 commenced business as an electrical engineer at Helsby without experience. The petitioning creditor is Mr. Archdale, engineer, from whom Lewis purchased a quantity of machinery, which he transferred to a company. With reference to some mutilations of a cash-book the bankrupt could not account for it, and thought he had a right to know who had pulled the leaves out of the book. The Company to whom his business was transferred consisted of a clerk in his employ, a traveller, two foremen, an electrician, and a pupil. He repudiated the suggestion that cheques belonging to the Wirral and Birkenhead Agricultural Society, of which he was the Secretary, had been paid into the electrical company's account. He had offered to set apart a portion of his income from the situation he now held in order to discharge his liabilities. There was no foundation, he said, for the attacks which had been made upon him in reference to his works at Helsby. At the conclusion of the examination, Mr. Sharp, the Official Receiver, asked that the watch and chain the bankrupt was wearing should be handed to him to meet the expense of the official note of the proceedings, as, although the liabilities were returned as £1,613, there were no assets, but the Registrar declined to make the order.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July* 16, 1892.

The Wright Type-Printing Telegraph.—This machine has just been brought out in this country. The messages are, as your readers will doubtless remember, transmitted by the operation of a keyboard similar in all respects to that of the ordinary type-writers, and they are received upon a sheet of paper eight inches wide, in the form of a type-written page instead of the usual tape. All the letters, numerals, fractions, and other characters necessary to type-writing are provided. In practice a speed of over 40 words per minute on a 200-mile circuit, using the ordinary Morse current, has been reached. It is announced that the United Press has adopted the machine for the distribution of its news throughout New York.

An Edison-Swan Interference Case.—A decision has been rendered by the Commissioner of Patents in the interference between Mr. Edison and Mr. J. W. Swan in regard to the patent for a certain form of incandescent lamp carbon. The decision, which is in favour of Mr. Swan, was made on appeal from the decision of the examiners-in-chief awarding priority to Mr. Edison upon both of the following interference issues :—First, a carbon formed from a straight strip of cardboard, paper, or parchment, and bent to form an arch, hoop, or loop, and carbonized by heat while in a bent condition ; second, a carbon for an electric lamp made of the parchment paper. It was at first thought that this decision of the commissioner in an interference for a patent for which application was made in 1880 might have some effect on the result of the decision in the filament case not yet decided, but which has been before the Court of Appeal for about two months. Inquiry of the companies' attorneys most likely to be concerned indicates, however, that no importance is attached to the question. It is said the process is of no particular value, and is not now used in the commercial manufacture of incandescent lamps. It is said Edison desired to have the satisfaction of seeing the patent interference decided in his behalf, and for this reason his attorneys continued to carry it up on appeal. The patent itself is regarded by the Edison attorneys as of no particular value.

Mr. Cyrus Field.—Among those who attended Mr. Cyrus Field's funeral services were many men who are prominent in the commercial world at the present time as well as others who were the leading financial men at the time of Mr. Field's triumph. Among those present may be mentioned Mr. Chauncey, M. Depew, Mr. Whitelaw Reid, Ex-Governor A. B. Cornell, Mr. Cornelius Vanderbilt, Mr. Henry Villard, Mr. W. E. Dodge, Mr. J. Pierpont Morgan, and Col. R. G. Ingersoll. A telegram of sympathy was received by the family from Sir James Anderson, the commander of the "Great Eastern" at the time the Atlantic cable was laid.

Storage Battery-Traction in New York.—The Second Avenue Railroad Company now operating its system by horses has made application to the State Board of Railroad Commissioners for permission to change its motive power from horses to storage batteries, and the hearing of this application is now going on in this city. The counsel for the railroad company stated at the opening of the hearing that if permission were granted a trial would be made of the new system on one of the company's lines running to the Harlem River at the north end of Manhattan Island. He stated that the total valuation of property along the line was $24,000,000, and that the consent of more than half the property owners had been obtained. It is understood that the system the company intends to try is the Waddell-Entz ; and although this was not mentioned at the hearing the characteristic features of the proposed system which were mentioned seem to indicate that this is the one contemplated. There was no opposition to the granting of the Company's petition, and the Board announced that its decision would be given later. In this connection it may be of interest to note that the King's County Railroad, an elevated structure in Brooklyn, N.Y., talks of making similar experiments. It is said that the matter has been carefully considered by the Board of Directors of the Company, and that they are strongly inclined to give the electrical method of propulsion a thorough trial.

CORRESPONDENCE.

THE DIMENSIONS OF PHYSICAL QUANTITIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : I do not propose to anticipate in your columns the discussion on Mr. Williams' Paper, but in the interests of that discussion one or two of "W. M. M.'s" points call for remark.

In the first place I hope that we may avoid a barren debate on the utility of mathematics.

In the next place I cannot understand how those who believe that $[\mu]$ and $[K]$ are concrete quantities, and who also believe that the dimensions of a co-efficient of self-induction are expressed by either of the equivalent formulæ $[L\mu]$ or $[L^{-1}T^2K^{-1}]$ can be accused of holding as a body the diametrically opposite view that self-induction "*is* a length." I can only say for myself that I have always regarded the use of the dimensional expression $[L\mu]$ as a direct denial of the statement that a co-efficient of self-induction is necessarily a length.

On another point it would be well for "W. M. M." to express himself more clearly. He asserts that [L], [M] and [T] are ratios.

Fourier (who first introduced the idea of dimensions) states that "the terms of one and the same equation could not be

Digitized by Google

compared if they had not the *same exponent* of *dimensions*" ("Analytical Theory of Heat." Trans. by A. Freeman, p. 128). Hence, to take a simple example, the equation

$$t[\mathrm{T}] = l[\mathrm{L}]$$

in which t and l are abstract numerical quantities, is false, even if the two sides are numerically identical. Will "W. M. M." explain why it is so, if it is merely the analogue of some such expression as

$$2 \times \frac{1}{5} = 3 \times \frac{2}{15},$$

in which all the symbols are abstract and the vulgar fractions correspond to the *ratios* [T] and [L] ?—Yours, &c.,

July 22nd, 1892. ARTHUR W. RÜCKER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Since you have been good enough to forward me Prof. Rücker's letter, perhaps you will allow me to consider it point by point before turning to the earlier letter by "E. M. C." and the criticisms with which you have favoured me.

Firstly, I must disclaim any intention of forestalling the discussion at the Physical Society. My Paper deals with a question antecedent to that of Mr. Williams, and the two debates could only clash should I convert the whole society to my views, which I am not sanguine enough to anticipate. I even resisted the temptation to discuss Mr. Williams' singular reasons for preferring the interpretation he adopts.

Secondly, I deprecate equally with Prof. Rücker a discussion on the utility of mathematics; and strongly suspect that in such a discussion we should be found on the same side.

I must acquit Prof. Rücker of holding the coefficient of self-induction is a length, and admit the force of his position that the view is inconsistent with holding [μ] to be a concrete quantity. But when I wrote I was not thinking only of this latest development of the school, but of all who regard the dimensional formulæ as—to quote Mr. Williams—"representing the *physical identities* of the various quantities . . . . just as the formula of a chemical compound indicates its composition and chemical identity." The quotation "but it *is* a length" is taken from a report of a sectional meeting of the British Association last year, as published in *The Electrician*, Vol. XXVII., p. 504. It was uttered by a prominent exponent of these views, who also regards Prof. Rücker's development of them with favour; and it is for him, not for me, to reconcile the contradiction. I am grateful to Prof. Rücker for this practical exemplification of the rather extreme statement, "What we get out changes from day to day"—a rhetorical phrase which I only allowed to stand because its exaggeration was too palpable to be unfair.

If I omitted to be as explicit as Prof. Rücker seems to desire, it was because I was writing an article, not a treatise, on Dimensions; and I assumed that both sides of the question would be tolerably familiar to your readers. But the question Prof. Rücker puts to me is easily answered. $t[\mathrm{T}] = l[\mathrm{L}]$ is not analogous to $2 \times \frac{1}{5} = 3 \times \frac{2}{15}$; for though [T] and [L] are ratios, they are not constants, they are independent variables, and the true analogue would be $2x = 2y$, where x and y are numerical quantities, but variable at will. I write $2y$ not $3y$, for any relation which is true when the dimensions are introduced is true also without them.

That one physical quantity varies conjointly as certain other physical quantities is a result of observation and experiment. If we wish to turn this variation into an equation between the measures of the various quantities *some* relation between the units of measurement must be assumed. The assumptions are usually made in such a way that the equation is true whatever fundamental units we start with. So we get a ready test of the soundness of any equation. Change the units how you will, subject to these rules, the equation remains true; if it can be made false, there is something wrong.

From the obvious analogy of a homogeneous equation of n dimensions, which, transform it how we may, must remain homogeneous, Fourier named these *change ratios* the dimensions of the units of the quantities. I should be obliged to Prof. Rücker if he can point to any evidence that Fourier meant more than this.

I need hardly tell "E. M. C." that I do not regard either the theory that electricity is ether (or any other of those enumerated) as a *valid* deduction from the study of dimensional formulæ; but I think the theory was suggested by the fact that the ratio of the two units of quantity is of the dimensions of a velocity, and that that velocity is nearly equal to the velocity of light. The theory is alluded to in Dr. Lodge's "Modern Views of Electricity," but I do not think there is there any hint of its origin. As we know that light is not ether, and are not sure whether electricity may not be, the latter theory is clearly more justifiable than the former.

I do not think the concrete view of units is any great safeguard against the confusion of thought shown in the drivel you quote from the "Book of Instructions, &c.," though the dimensional equations, on either interpretation, afford, perhaps, the readiest way of exposing such confusion. Must I repeat again that I do not consider these equations useless?

I was under the impression that the quantitative relation between E. S. and E. M. units was a matter of experiment, and I fail quite to see your point, when you urge the failure of text books to describe the method of finding it satisfactorily as a reason for regarding a numerical interpretation of units insufficient.

That such relations as "the ratio of a cubic foot to a pound" [? ounce] are unintelligible has been my contention throughout, and it is to avoid such that I would keep concretes out of the equations. Of course no equation can be intelligently interpreted without bearing in mind of what the numbers involved are measures; significant symbols are a great, and legitimate, help in this. To treat the symbols themselves as concretes is little additional help, and tends to introduce confusion and make the equations talk nonsense.

I venture to forward you a "parable," which, on this, and on the educational question, may help your readers to understand my position more readily than any heavy argument could do.

A PARABLE.

Once upon a time a schoolboy was endeavouring to solve a certain equation, and this is what he wrote down on his slate:—

Let $x = \text{oxen}$, $y = \text{sheep}$, $z = \text{rabbits}$;

then $$x + y + z = 100, \quad . \quad . \quad . \quad . \quad . \quad . \quad \text{(i.)}$$

and $$5x + y + \frac{z}{20} = £100 \quad . \quad . \quad . \quad . \quad . \quad \text{(ii.)}$$

A humble individual in a black gown, possessed of a university degree, a delicate sense of the niceties of language, and little else, came up at that moment, and, with the mild sarcasm that is the modern substitute for the rod, suggested that you could not very well add together these multiples and fractions of animals, and equate them to a sum of money. The boy felt that he was being blamed unjustly. He could not, of course, put his feelings into words, not having arrived at that stage of mental development which admits of an argument being coherently stated; but his feeling was that he knew what he meant, and that the first line in his solution was intended as a memorandum rather than as an exact statement. What he could do was to finish his problem, and triumphantly inform his master that the result came out all right. He was then told that the criticism applied to the form of his statement of the question, not to the algebraical work, and that slovenly statement was apt to lead to slovenly thought. The boy thought that all rot, but being an obliging fellow he condescended to substitute:—

Let x = the number of oxen.
" y = " sheep.
" z = " rabbits.

And to *suppress* the symbol £ in (ii).

Anyone who knows the average schoolboy will admit that a lad who at fifteen can tackle an indeterminate equation, and who is so ready to yield his superior judgment to the prejudices of his elders, is sure to get on, and stand high in the

Digitized by Google

class lists in mathematics. His genius is also likely to be most appreciated at home, where it is least understood, and his father will probably look out for a career for him which will give his special talent full play.

Accordingly, two years later, we find our schoolboy a student in a technical college under charge of a professor who is in all, save a tendency to sarcasm, the very opposite of his former instructor. He has learnt by this time to appreciate for himself the importance of accurate statement as a help to accurate thought; and he is engaged in the elementary task of ormulating Ohm's law. He writes:—

Let E be the number of volts in the E.M.F. of a given circuit.

R the number of ohms in the resistance of the circuit.

Then $\frac{E}{R}$ = the number of amperes of current flowing in that circuit = C.

The Professor comes up and shakes his head. "You are dealing with concretes," he says. "This is *a physical equation* —write

"E volts ÷ R ohms = C amperes,

or, $\frac{\text{E.M.F.}}{\text{resistance}}$ = current."

Suddenly the student remembers those unhappy fragmentary rabbits, and bursts into unseemly laughter. Apology is vain, and explanation impossible, and he is excluded from lectures for a week.—Yours, &c., W. M. M.

[Our allusion was not to the *experimental* determination of the ratio of the E.S. and E.M. units, but to the theoretical connection between the numbers representing in the two systems some electrical quantity such as capacity, and the number representing r.—Ed. *E.*]

THE ACCOUNTS OF THE METROPOLITAN ELECTRICITY SUPPLY COMPANIES.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In the interesting analysis of the accounts of the Metropolitan Electricity Supply Companies which you publish in your issue of the 8th inst. you call attention to the fact that the alternating-current companies spend rather more than twice as much as the continuous-current on coal per unit supplied. May I suggest that some additional information might be furnished which would help us to form a better basis of comparison between the two systems than the expenditure on fuel per unit supplied alone? The essence of electricity supply is *distribution*; and the information is not complete unless the cost of the watts supplied is supplemented by some information as to the distance which they are delivered, what are the present relative areas of supply of these distributing stations, or what is the average distance to which each unit is sent. With a map showing the mains and the positions of the consumers and a list of the consumers' meter readings for 1891, it ought not to be very difficult to find the mean radius of supply. If we can consider the squares of these radii side by side with the other figures given in your table, we ought to be able to get a better idea of the relative economy of the two systems; at least, it will be possible to judge whether it is fair to compare them at all.—Yours, &c., Edward W. Cowan.

Bowdon, Cheshire, July 20, 1892.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

Tenders Invited.—Our readers are reminded that the tenders for wiring the Town Hall, Hull, are to be sent in by Friday next, the 5th August.

Tenders Received.—The following tenders have been received by the London County Council for lighting Claybury Asylum by electricity, and have been referred to the Asylums Committee:—

Siemens Bros. and Co. (Limited)	£28,400
Messrs. Laing, Wharton and Down	27,982
Messrs. B. Verity and Sons	26,471
Ropers' Electrical Engineering Company (Limited)	23,966
Messrs. Paterson and Cooper	22,540
Messrs. J. D. F. Andrews and Co.	21,000
Fowler, Lancaster, and Co. (Limited)	20,549
Messrs. Drake and Gorham	20,500
Electric Construction Corporation (Limited)	19,932
Messrs. Hammond and Co.	19,900
Mather and Platt (Limited)	19,250
Messrs. Johnson and Phillips	19,200
Manchester Edison-Swan Company (Limited)	18,850
Messrs. Bourne and Grant	18,808
Messrs. Sharp and Kent	18,540
Messrs. J. D. Statter and Co.	18,128
Edmundsons (Limited)	17,737
Crompton and Co. (Limited)	17,500
J. E. H. Gordon and Co. (Limited)	17,337
Messrs. Appleton, Burbey, and Williamson	16,500
Brush Electrical Engineering Company (Limited)	15,800
Latimer Clark, Muirhead, and Co. (Limited)	15,130
Mr. F. M. Newton	14,105
Woodhouse and Rawson United (Limited)	13,970

The Holbeach Local Board on Thursday last week opened tenders which had been received for lighting the streets by electric light, gas, or oil, the latter illuminant being finally chosen.

Tenders Accepted.—The Electrical Committee of the Bristol Town Council have accepted the tender of Woodhouse and Rawson United (Limited) to supply the condensing plant for the large electric light installation in progress, for the sum of £3,752. The Council also decided to take the opinion of their engineer upon various suggested improvements in the posts to be used for the public lighting.

Appointment Vacant.—The Dundee Gas Commissioners desire to secure the services of an electrical engineer to inspect the works during construction and to manage the same after construction.

Messrs. King, Mendham and Co.—This firm have obtained the contract for the electric lighting of the new offices of Messrs. John Lysaght (Limited), St. Vincent Iron Works, Bristol. The installation will consist of 110 lamps, and these will be run either direct from the dynamo or from a set of accumulators.

Plant for Sale.—Messrs. Wheatley Kirk, Price, and Goulty have for sale a quantity of useful plant, all by well-known makers, including several small vertical and horizontal engines, with and without dynamos. Further particulars are given in our advertisement columns.

Trowbridge.—At a meeting of residents on Thursday last week it was decided to request the Local Board to endeavour to get the Local Government Board to either take up the matter of the electric lighting of Trowbridge, or to modify their present unfavourable attitude to a private company making the installation.

Bacup.—The Corporation have been making inquiries amongst the tradesmen and others as to the likelihood of their adopting the electric light in case the Corporation should furnish the necessary plant. The Corporation's powers to supply electricity for lighting purposes will expire next month.

Werrington (Staffs.).—At the quarterly meeting of the Staffordshire County Council on Tuesday last, the Industrial (Boys) School Committee asked the sanction of the Council for the adoption of electric lighting at the Werrington Industrial Schools, in preference to the present system of lighting by oil lamps. It was estimated that the outlay required would be, including buildings, from £835 to £926, and the annual cost of maintenance and depreciation from £80 to £90. In spite of some opposition the Council decided in favour of lighting by electricity.

Weybridge.—At a meeting of inhabitants on Thursday last week Col. Martindale, chairman of the Laing, Wharton, and Down Construction Syndicate (Limited), explained at some length what the Syndicate proposed to do in regard to the electric light at Weybridge, and a committee was appointed to confer with the Directors.

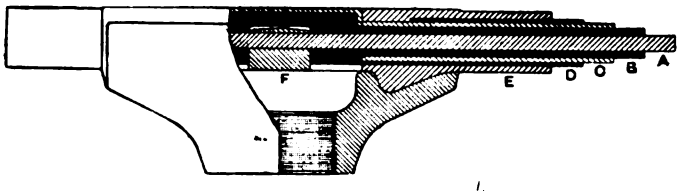
St. Mary's Cathedral, Newcastle-upon-Tyne.—This cathedral has just been fitted up for the electric light by Messrs. R. J. Charleton and Co., who have replaced each of the old gas lamps.

Digitized by Google

with a 100 c.p. incandescent lamp, the current being supplied by the Newcastle and District Electric Lighting Company (Limited).

SURVEYORS' INSTITUTION, LONDON.—The electric light is about to be installed at this Institution, under the superintendence of Messrs. Morgan Williams and King, the contractors for the work being Messrs. Pyke and Harris.

MAVOR AND COULSON'S CONCENTRIC WIRING.—In *The Electrician*, Vol. XXVII., p. 183, we described several details of this concentric wiring system, and we illustrate a new junction box, of which a sample has been sent to us. This consists of a brass box with necks to take the main conductor. These necks are enlarged into pockets in the brass casting, and fusible metal is run in, making connection with the outer conductor. In the sample which we have received the outer conductor consists of a spirally-wound copper tape, and over this is a thin insulation and a lead covering. The illustration shows the central conductor A, a fibrous impregnated insulation B, a spiral tape conductor C, thin insulation D, and a lead covering E. A contact piece F soldered to the central conductor, and backed by a disc of insulating material, is provided for making a butt joint with the branch conductor. The outer connection is made through the brass casting, into which a nipple is screwed. By slacking off a jam nut the branch may be unscrewed and removed. Distributing boxes and other details have been made, and the advantage is offered that all fittings, &c., may be wired complete before erec-



tion, being merely screwed together in place. We understand that the requirements of the Phœnix Office are met; and if the earthing of the middle conductor of the three-wire system becomes general this mode of wiring ought to be widely adopted. Messrs. Mavor and Coulson have forwarded us drawings showing various other details, the conductor being provided in some cases with a stranded wire sheath as well as a lead covering. Special arrangements of the system have been made to suit the requirements of the Home Office for the dangerous portion of the dynamite factory of Nobel's Explosives Company.——This firm have acquired the business of engineers and machine makers lately carried on in Glasgow by Messrs. Kellock and Galbraith.

MESSRS. CURTIS BROTHERS.—This firm have opened premises at 10, Suffolk-street, Dublin, where they intend carrying on business as electrical engineers and scientific instrument makers.

MESSRS. EVANS, STEWART, PALMER AND CO.—This firm have secured the contract for fitting up an electric light installation at the offices of the Gophir Diamond Company, Regent-street, W.

ANNUAL OUTING.—Mr. Edward Gimingham, the manager of the Edison and Swan Company's works at Ponder's End, entertained the works staff, numbering 54, to dinner at the Rye House on Saturday last. The weather was all that could be desired, and a most enjoyable day was the result.

FIRE IN CHANCERY-LANE.—Mr. C. Purcell Taylor, D.Sc., writes to inform us that, although all his apparatus was destroyed in the fire on Friday, his library is intact, and the most important of the Government and private papers have been saved.

MR. ARTHUR STANBURY.—This gentleman has just completed on the premises of Mr. J. M. Coole, Douglas, practically the first private electric light installation in the Isle of Man. The plant comprises a Norwich dynamo, driven by a gas engine. The lights are distributed throughout the warehouse, shop, and residential portions of the building, and consist of 26 16 c.p., four 25 c.p., and four 50 c.p. Edison-Swan lamps. Mr. Stanbury has also recently fitted up Messrs. Singer's Stall at the Exhibition now being held in Douglas.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

June 20, 1892.

11,487. R. F. JEFFRIES. London. An apparatus for erecting top and middle sections of telephones and other poles.

11,525. G. G. M. HARDINGHAM. London. Apparatus for use in manufacturing electric cables. (Felten and Guilleaume, Germany.)

11,526. G. G. M. HARDINGHAM. London. Improvements in electric cables. (Felton and Guilleaume, Germany.)

11,528. J. A. C. ZIEGLER, W. R. RUTLEDGE, and F. E. ALLAN. London. Improvements in dynamo-electric machines and motors.

11,532. W. A. BOESE. Liverpool. Improvements in secondary or storage batteries.

June 21, 1892.

11,548. C. S. SNELL and WOODHOUSE AND RAWSON UNITED (LIMITED). London. Improvements in connection with lubricators used on dynamo-electric and similar machinery.

11,592. C. K. MILLS. London. Means for operating ammeters and other electrical apparatus. (H. M. Pilkington and R. S. White, United States.)

11,617. C. J. HALL. London. Improvements in or relating to dynamo machines.

11,624. H. H. LAKE. London. Improvements in coin-operated telephone apparatus. (E. Noreiga, Mexico.)

11,634. F. WYNNE. London. Improvements in or relating to electric railways.

11,640. F. H. NALDER, H. NALDER, C. W. S. CRAWLEY, and A. SOAMES. London. Improvements in electric meters.

June 22, 1892.

11,664. E. PAYNE. London. Improvements connected with tubular electric conductors and their insulation.

11,672. R. E. B. CROMPTON and S. L. BRUNTON. London. Improvements in armatures for alternate-current dynamo-electric machines and motors.

11,692. F. PURDON, H. E. WALTERS, B. MOTT, and J. P. O'DONNELL. London. Improvements in electric locomotives.

11,698. F. MEYER. London. Improvements in insulators for overhead and other electric wires.

June 23, 1892.

11,736. J. SWINBURNE. Teddington. Improvements in and connected with electric dynamo machines, distribution by means of transformers, organs, and the reduction of zinc.

11,779. G. F. REDFERN. London. Improvements in the manufacture of carbons for electric arc-lamps. (Carl Braun, Germany.)

11,807. R. KENNEDY. Glasgow. Improvements in and relating to the measuring of electricity, and in meters therefor.

11,822. H. ARON. Liverpool. Improved means for electrically winding up the weight for driving clockwork and other mechanism.

11,833. H. ARON. Liverpool. Improvements in apparatus for measuring electric currents.

11,835. E. J. FINOT. London. Improvements in the process and apparatus for tanning hides and skins with electrolytic action.

11,849. S. BERGMANN. Glasgow. Improvements in distribution and branch boxes for electric circuits.

June 27, 1892.

11,941. H. W. MILLER. London. Improvements in electricity meters.

11,948. H. CORTLAND. London. Improvements in electric fire-alarm and circuit controlling thermostat and clock mechanism.

11,952. J. W. JONES. Balham. Improvements in electric meters.

June 28, 1892.

11,969. J. H. HIRST. Kingston-upon-Hull. Telegraphic (including telephonic) communication between lightships and the shore.

2,039. T. FLOYD. London. Improvements in the construction of electric railways and appliances therefor.

12,040. J. E. A. GWYNNE. London. Improvements in and connected with arc electric lamps.

12,044. G. H. JONES. London. Automatic supply of electricity.

June 29, 1892.

12,087. F. W. SCHINDLER-JENNY. London. Improvements in electric heating devices, and contacts for the same.

June 30, 1892.

12,191. B. J. B. MILLS. London. Improvements in electric railways. (E. H. Johnson, United States.)

July 1, 1892.

12,212. J. M. BRADFORD. Portland. Electric regulating apparatus.

12,238. B. SCHERTHANER. London. Improvements in and apparatus for producing and utilising electric currents.

12,246. Y. A. M. P. GOUBAUX. London. Improvements in electrica meters.

12,258. P. SCHARF. London. Improved electric glow lamp.

July 2, 1892.

12,295. W. HABGOOD. Buckingham. Improvements in electric arc lamps.

12,306. J. B. LEE. London. Improvements in the construction of secondary batteries for electrical storage purposes.

12,311. C. DARRAH. Manchester. Improvements in electric theft-prevention alarms.

July 4, 1892.

12,359. F. F. BENNETT and H. CURWEN. Preston. Working by electricity weaving and spinning machinery.

12,381. E. B. BRIGHT and M. BAILEY. Esher, Surrey. Improvements in the manufacture of plates for storage batteries or accumulators, and the accessories thereto.

Digitized by Google

12,382. R. D. Sanders. London. Improvements in the manufacture of wire, strips and the like by electro-deposition.
12,396. J. A. Timmis. Westminster, London. Improvements in the lighting of railway trains electrically.

July 5, 1892.

12,397. J. Sayers. Derby. An improved method of regulation of the potential difference of electrical conductors, more particularly with regard to the variation caused by the varying current in the middle or "third" wire of a three-wire system.
12,417. W. Mitchell. London. Electric brazing and soldering devices.
12,436. H. H. Lake. London. Improvements in electric insulators. (L. McCarthy, United States.)
12,442. L. D. Adler, J. Loewenburg, S. Young, and M. Moskowitz. London. Improvements relating to the lighting and heating of railway and other vehicles by electricity.

July 6, 1892.

12,468. J. Edmundson and J. Oulton. Halifax. Improvements in electricity meters.
12,476. F. Brown and A. Cheetham. Walsall. An improvement in induction coils for medical purposes.
12,506. R. H. Jones. London. A new improved telephone transmitter.
12,511. E. Willans, widow and administratrix of the late P. W. Willans. London. Improvements in electro-magnetic clutches.

July 7, 1892.

12,528. G. L. Anders and W. Kottgen. London. Improvements in telephonic apparatus and switches.

July 8, 1892.

12,618. L. Schramm and S. T. Wyand. London. An improved combination wall socket and switch for electric currents.
12,619. L. Schramm and S. T. Wyand. London. An improved electric switch.

July 9, 1892.

12,655. P. Willis. London. Improvements in conduits for electric or cable-roads. (C. H. Bates, W. A. Miller, and W. Ragan, United States.)

July 11, 1892.

12,691. S. F. Walker. Cardiff. Improvements in electro-magnetic apparatus for controlling electric light and power circuits.
12,700. D. W. Peaks. Northampton. A new or improved apparatus for carrying or conveying telegraph or telephone wires over houses or buildings.
12,731. Siemens Bros. and Co. (Limited). London. Improvements in electrolytic extraction of zinc. (Messrs. Siemens and Halske, Germany.)
12,735. J. C. Fuller and G. Fuller. London. Improvements in supports for telegraph insulators.
12,737. T. Jenner and G. B. Wilkes. London. Improvements in electrical switches and incandescent lamp holders.

July 12, 1892.

12,745. H. J. Allison. London. Electric signalling apparatus. (The Standard Electric Signal Company, United States.)
12,759. W. P. Thompson. Liverpool. Improvements in or relating to electric railways, especially those in which underground conduits are used, and in rolling stock for the same. (A. H. Hieatzman and H. D. Hieatzman, United States.)
12,807. A. W. Money and H. Nash. London. Improvements in apparatus for regulating the arc in electric arc lamps.
12,818. J. E. Evans-Jackson. London. Improvements in conduits for electric railways. (C. L. Travis, United States).

COMPANIES' MEETINGS & REPORTS.

Eastern Telegraph Company (Limited).

The fortieth half-yearly ordinary general meeting of the Eastern Telegraph Company (Limited) was held on Friday, July 22, 1892, at Winchester House, 50, Old Broad-street, London, under the presidency of Sir John Pender, K.C.M.G., M.P.

The SECRETARY (Mr. Draper) read the notice convening the meeting and the minutes of the last general meeting.

After signing the minutes, and the report and accounts having been taken as read,

The CHAIRMAN said: I will make a few remarks, as I have generally done at the many meetings at which I have had the pleasure of addressing you. The gross revenue for the half-year under review amounted to £382,207, as against £383,307 in the corresponding period of 1891, or a decrease of £1,100. The small decrease of £799 in the message receipts is principally caused by the loss of revenue from the reduction in the Australian tariff, and by small decreases in the receipts from other sources, notably South Africa; but these reductions have been almost counterbalanced by the growth of traffic in other directions. The revenue from our investments in other companies, with the exception of the Direct Spanish Company, remains the same.

The total ordinary expenses for the half-year ended March 31, 1892, amounted to £105,820, as against £102,020, or an increase of £3,800, the details of which are as follows:—General expenses in London £9,589, as against £9,503, or an increase of £86. The working expenses at the stations were £78,695, as against £75,003, being an increase of £3,692. The principal increases are in salaries, rent, fuel and light, repairs and renewals of furniture, and repairs to stations, &c. The first item is due to an increase in the number of our foreign staff to work the Aden-Bombay triplicate cable, and to cope with the increased number of messages caused by the reduction of tariff to Australia and the normal growth of traffic. The number of messages carried in 1890 was 1,276,368, and in 1891 1,399,755, or an increase of 123,387, so that we are not going back. A portion of the increase is also due to the ordinary promotions, which depend in a great measure upon the clerk acquiring a certain standard of speed and accuracy in his work. Our policy has always been to improve the speed and accuracy of all classes of traffic, whether we are in competition or not; and we believe this object can be best attained by encouraging our staff to do their best, and rewarding those who show the best results. Our experience goes to prove that the more we can improve the service rendered to the telegraphing public, especially as regards speed and accuracy, the greater will be the number of messages sent.

Additional accommodation has been necessary for the increased number of staff, and important improvements have been effected at several of the stations, which will materially add to their comfort: and, with a due regard to the health of the staff, the sanitary arrangements have been carefully inspected, and improvements carried out wherever it has been considered necessary to do so. I need not tell you that if we were to take up our stations abroad and occupy them as we first found them they would not prove very wholesome homes for our staff. We have always thought that if we are to get good work we must put our staff in as comfortable and healthy positions as possible, so that there will be no sanitary drawbacks in connection with the work they have to do. I believe that throughout the Levant at the present moment where we have stations they are in as satisfactory a condition as possible, so far as regards sanitation. We are pleased at being constantly complimented about our stations; and visiting them sometimes, as I do, I am very glad to say that our stations are such that we have just reason to be proud of them, and, comparatively speaking, we have considerably below the average of cases of disease. We are gainers in the long run by this, because a sick clerk costs us a good deal of money, while a healthy clerk gives us better work, and consequently the more satisfies our requirements.

Included in this half-year's figures is a sum of £4,000 carried to the maintenance ships reserve fund, against £3,000 in the same period of last year, or an increase of £1,000. The expenses attending the repairs and renewals of cables amounted to £53,515, as against £53,144, or an increase of £371. As will be seen from Abstract C, our ships have been fully employed carrying out the important work of repairs and renewals, not only for our own account, but for account of the Brazilian, the South African, the African Direct, and the Direct Spanish Companies. I was asked the question last year whether our repairing ships obtained any return or profit out of these repairs, and I am therefore glad to be able to tell you that this half year the money accruing from these repairs has given us something like £15,000.

A very expensive repair was effected in our original Aden-Bombay cable and a considerable length of new cable was laid in, which will add to its efficiency and give it longer life. We are getting into a period when we have to look to the life of these cables. We have expended a great deal of money on them out of income in the last twenty-one years, and the additions which we have thus made to our cables give us hope that we shall prolong their life for a very considerably longer period than we expected when we first began our work.

Digitized by Google

After providing the usual amounts for interest on debentures, debenture stock, and preference shares, we are able to propose the usual final dividend of 1½ per cent, and bonus of 1½ per cent., making with the interim dividends already paid a total distribution of 6½ per cent. for the year ended March 31, 1892, and carry the sum of £68,000 to the reserve fund. I think you will agree with us that that is a very satisfactory state of things, and it shows, I think, that you have behind your investment something that will back it up, and enable us to go on with our work, doing it efficiently, and still maintaining what we consider in these days a very good dividend indeed.

After applying from the reserve fund a further sum of £72,773 towards the cost of the Aden-Bombay triplicate cable and other expenditure, the general reserve fund amounts to £442,014; and the total sum applied from this fund for new cables, &c, now amounts to £1,174,235. You therefore see that we have been using our reserve fund in a way largely to increase our system, while keeping down the capital and still maintaining the payment of good dividends.

Now, gentlemen, I come to a question which I think you were all pretty unanimous on when I last addressed you, namely, the fund for the benefit of our *employés*. We have brought that now, practically, I may say, to a conclusion. We have threshed it out thoroughly. We have had advice from the best actuaries of the day on the matter, and we have come to the conclusion that what we are going to do is for the benefit of our staff, and to make our service one of the most popular of any class of industry in the country. In this particular industry, as I have before stated, we require honest, intelligent, bright men; and unless we show some inducement for the future we cannot have that class of men. Our staff, I may say, are thoroughly satisfied with the course we have taken. We have consulted the leading members of our staff as to the best way of dealing with this question, and the whole thing has now been threshed out, and is in a thoroughly satisfactory position. I am, therefore, going to ask you to pass a resolution empowering us to bring the whole question into practical working. A full and complete statement of the whole business can be seen by any shareholder at the office, or it is on the table if anyone wishes to look through it after the meeting. It is, however, too long for us to go into in detail; but you have trusted us so long that I dare say you will not withhold from us your confidence to day in regard to this matter after what I have told you.

Mr. BAINES: I think that we ought to have some outline of the details of the proposal.

The CHAIRMAN: I think I can shorten the proceedings a little by condensing what I intended to say on the matter. The shareholders having at the last meeting approved the principle of establishing a staff pension fund, your Directors have had a scheme prepared by experienced actuaries, who advise that an annual contribution by the Company of 2½ per cent. on the salaries, and a similar contribution by the staff, would, if invested at 4 per cent. compound interest, provide sufficient funds to make adequate retiring allowances for the younger members of the staff on their attaining 60 years of age; but as many of the older *employés* have already seen considerable service, and their retirement in some cases cannot be far distant, 2½ per cent. would be insufficient to place them on an equally favourable footing. With a view, therefore, to supplementing their allowances from the pension fund, the actuaries advise that, in addition to the 2½ per cent. just referred to, the Company should continue their present contribution to the endowment assurance fund in full until all the existing policies are paid off, and allow the savings effected by the premiums ceasing to be payable to the assurance company, as the policies mature from time to time, to be applied exclusively for the benefit of the older servants. The wish that the older servants should not be placed on a less favourable footing than the younger members of the staff was strongly expressed at the last meeting. The actuaries further recommend that the Company should guarantee 4 per cent. interest on the accumulations of the fund. Provision is also made in the actuarial calculations for dealing with cases of death or breaking down in health before reaching the retiring age, and for other contingencies. This is a fair outline of the actuaries' scheme; but as certain details are still under consideration by the Board, it is proposed to ask you to-day to approve a resolution in general terms empowering your Directors to bring the scheme into operation when the details are finally settled. The report of Messrs. Neison and Schooling to which I have referred is laid on the table, and as it is a long and elaborate document it can be seen at any time at the Secretary's office. You have now got to know about as much as we do ourselves concerning this matter. The whole scheme is based upon sound principles. We have employed the best actuaries to deal with it, and what we ask from the Company is not a very excessive sum, and we believe that it will help our staff in their duties and make them look forward to a brighter prospect in future, while we shall continue to pay a good dividend.

I think I have now said pretty much all that is necessary to be said in regard to details, but I may add two or three more words. Looking at the notes of our meetings for the last two or three years I find that I have given you such an amount of information that I am satisfied when you come here six months after six months you find that you know thoroughly the working of this great Company. We have given you every information, and kept nothing back. We have felt that if we are to be strong ourselves we must be strong through the support of our shareholders. We have acted on that principle. I do not believe there is any company that can show a better or more satisfactory position in England.

Our general telegraph system is working well, but I cannot say that there is any time when it is throughout in perfect working order. Still, all our system is under such control that there is no fear in regard to the maintenance of our communications. We have duplicate and, in some cases, triplicate cables, and we are therefore able to carry on our system so satisfactorily that you will be astonished, looking at the large amount of work involved by our system, when I tell you that we have only had one letter regarding this meeting to-day, and that of a complimentary nature. So satisfied is the gentleman who wrote this letter that he would travel a considerable distance if he thought it were necessary to come and support the Directors. We have had no letter of complaint of any kind.

We hear whispers abroad that the merchants think that our tariffs ought to be reduced. We, however, understand our business thoroughly, and I think that if the merchants came in a deputation to us about this matter, I should be able to satisfy them that we have done them a great deal more benefit by our system than we have received from them. I have been a merchant for 50 years of my life, and I know all the ins and outs of mercantile life. I know how enormously beneficial to the general trade of the country this submarine telegraph system is, and the merchants have got the full advantage of it, and it is so cheap in view of its great benefits that it makes a comparatively small item to what it did a few years ago in their expenses. Every man must be paid for his labour. We have met every case which we felt that it was our duty to meet with a view to extend the traffic. I think we have been successful in what we have done, and I believe I may say, without hesitation, that nine-tenths of the great operations of this Empire are begun and ended by telegraphic communications. I thank you for listening to me as you have done, and if any gentleman has any question to put I shall be glad to answer him. I will, however, first propose the resolution, which is as follows:—

"That the printed report and accounts of the Directors to 31st March, 1892, submitted to this meeting, be and the same are hereby received and adopted; that a dividend on the preference shares of the Company to 30th June, 1892, at the rate of 6 per cent. per annum be paid, less income tax; and that, in accordance with the Directors' recommendation, a dividend be and is now declared of 2s 6d. per share, with a bonus of 3s. per share, both free of income tax on the ordinary shares of the Company, making, with previous payments by way of dividend on account, a total payment of 6½ per cent. on those shares for the year ended 31st March, 1892."

The VICE-CHAIRMAN (the Most Hon. the Marquis of Tweeddale): I beg to second that.

The CHAIRMAN: If any gentleman has any question to ask I shall be glad to answer him.

Mr. ROBERT SNARE: I wish to ask if you have any idea of the amount that will be required for this pension fund. I only ask the question as it will go before the public and the shareholders, and it will be satisfactory to them to know that it is such a small sum; and we may be pleased to grant more if it is necessary.

The CHAIRMAN: It will cost us about £2,000 more than we are paying at the present moment.

Mr. BAINES: You have all heard what the Chairman has said. You have noticed that there is a little falling-off in some respects in our revenue, with an increase in the expenditure. I joined this Company a great many years ago, when it was in sections; and prospects were then held out of 10 per cent. and 12 per cent. We have, however, never realised those dividends—not that I am going to charge the Board with any want of ability, for they have had to meet circumstances which they could not foresee; but now that the Company has got in a prosperous condition it is paying, I admit, a fair dividend, although I do not think it is by any means an extravagant return, considering the risky nature of the business. You may get to-day perfectly safe debentures to pay you 4 per cent., and for the risky character of our business we get this 2½ per cent. extra. There is a tendency in the present age to make every company a sort of popular institution. I have myself been employed by firms, but I have never found them help me in the way suggested, or hold out any such prospects to me in regard to the future. The difficulties of certain companies are very serious. The Great Eastern Railway Company at the present time is showing a marked falling-off in its dividend, and why? Because wages have increased and materials have increased, and the consequence is there is less money to divide. I should think it would be wise on the part of the Directors if they were to postpone this matter—at all events, until such time as we have the complete scheme before us. I hope that the Directors will take this suggestion into consideration. I do not consider that this dividend of 6½ per cent. affords any ground for being proud of our position. It is a very fair return, but I do not think it is anything to go into ecstacies about.

The CHAIRMAN: The solicitor reminds me that the whole thing is complete, and only requires this resolution to be passed to carry it into effect.

Mr. BAINES: That may be, but we have not the complete scheme in our mind.

The CHAIRMAN: If you want to get this complete scheme into your mind you had better spend a couple of hours at the office, and you can satisfy yourself. I am quite sure that were I to read that document to-day, and spend all the time that would be necessary to do so, a great many of us would not be much wiser at the end than they are now. We have taken the best people into our confidence, and have done everything we possibly could to establish a fair and just system. I should myself deeply regret if I could think that in after years, when a younger class of people are here, and probably a younger class are addressing you, there should be any reflection thrown upon myself or my colleagues for having done anything unjust either to the shareholders or to those who serve us. The whole system is based upon justice, and upon that justice we stand; and I am perfectly satisfied in the course we have taken, knowing that the men I am addressing will back us up. On the last occasion I addressed you we were pressed to go on with this scheme. The feeling was so strongly in favour of it that we did not hesitate. Now, this gentleman throws doubt upon it—not that I attach any value to his doubts, because I am sure that the shareholders will support the Directors in passing this resolution to-day, and unanimously.

Mr. JOHN NEWTON: I should like to say a word or two. Years ago when I first became a shareholder our property stood at 7½ in the

Digitized by Google

market, and we were receiving disappointing dividends—5 per cent. I was one then who thought that we ought to have a dividend something like what had been promised to us in the prospectus; but events move on, notwithstanding prospectuses; and you know that the merchants of this country, and of every other country, too, are very clever, and can circumvent you in your ideas about 15 per cent. dividends by what they themselves can do. Moreover, the various Governments have come and said that we must reduce our tariffs. In spite of all that, what has taken place? You see your property since then doubled in value, and it is now established on such a basis that it ranks among the highest class of investments. In old days it was said that your cables would only live 10 or 12 years, but I always said 20 years; and certainly their life has been greatly prolonged beyond what was at one time thought would be the case. Not only has your property doubled in value, but it stands at that value and has done so for some time. I do not know how long ago it is since our shares got to 15, but I believe they have been for the last two months standing steadily at that price. Look at the advantage of that—of your having a solid steady property, upon which you are getting a dividend of 6½ per cent. You may say, what is 6½ per cent. in comparison with the dividends that are paid elsewhere—that were paid years ago by many other companies? But where are those companies now? Where is the position of a great many investors now compared with what it was a few years ago? Probably no class of security stands higher than telegraph property now; and I say that the staff who have worked for you in foreign parts ought to be most jealously and well looked after, and when they go out to their service they ought to be well looked after by you. It is a very different service from that of a man who works for a railway company. Remember you have no union to contend against. If you had a property that unionists could interfere with, you would have to give up some of your dividend to that influence. I think that we have every reason to be satisfied and proud that you have brought forward this scheme in recognition of the services of the staff who work for you, and it will give the staff a greater interest in the Company. The 2½ per cent. which the shareholders are now asked for, as the Chairman has mentioned, is a fleabite compared with the advantages which we may expect to derive from the scheme.

The CHAIRMAN then put the resolution that the report and accounts be received and adopted; and declared it to be carried unanimously.

The CHAIRMAN: I now propose—

"*That the report of Messrs. Nelson and Schooling, of the Institute of Actuaries, relative to the establishment of a staff pension fund having been submitted to the meeting, the Directors be and they are hereby authorised to cause such deed or deeds or other documents to be prepared as they may consider necessary for carrying out the scheme embodied in the said report, with such alterations and modifications, if any, as may be approved by the Directors.*"

That is the resolution which I now propose with respect to the fund for the staff. The resolution will be seconded by Sir James Anderson, who takes a very deep interest indeed in the staff, and who, I am perfectly satisfied, considers that the decision which his Board has come to is a just and fair decision, having reference to the thoroughly efficient working of the concern, and working it through good and reliable heads.

The MANAGING DIRECTOR (Sir James Anderson): In seconding this resolution I will just say one or two words. A very great feature of our service is the necessity of keeping our young men with us when they become proficient. They learn to become proficient, and then a great many leave us for other professions, and the loss of these men is a decided loss to us and the shareholders. I have favoured this pension scheme more on that account almost than anything else, because it will knit our young men to our interests and to the service, and make them proud of the Company to which they belong. I second the resolution with very great pleasure.

The CHAIRMAN: Those in favour of the resolution will please to hold up their hands. To the contrary. Carried unanimously. I think that that concludes the business of the meeting; and I am pleased to find that the feeling so strongly expressed six months ago is so unanimously confirmed to-day. It will carry to the staff a gleam of sunshine which, you may depend upon it, will benefit your interests while you are benefiting theirs, and will add considerably to the strength and prosperity of this great Company of which we are so proud.

Mr. NEWTON: Before the meeting separates I propose a vote of thanks to the Chairman and Directors; and I congratulate the Chairman on the success which he has just achieved in the northern part of this island. I may be trespassing, perhaps on dangerous ground, but I cannot refrain from expressing the hope that your services there, Sir, will be as successful as they have been here.

Mr. SNARE: As an old shareholder, I have great pleasure in seconding the resolution.

The resolution was carried unanimously.

The CHAIRMAN: I thank you very sincerely for this vote and for the kind words which have been said in regard to myself. Of course, we do not know any politics in this Company, as a company. I dare say many of my friends thought I was a very bold man in having entered rather actively into political life at the present moment; but I have had a good deal to do with building up this great Empire. I have had fifty years of a pretty active life, and I think I find the country better and greater and more respected throughout the world to-day than it was fifty years ago. I should not like, even at my time of life, to take any part in pulling down that Empire; and while I have got a little vigour, a little courage, and a little life left in me it will all be devoted to the maintenance of the Empire, and, in connection with it, this great telegraphic system of ours, which has done more to knit the world together than anything else.

The proceedings then terminated.

West African Telegraph Company (Limited).

The seventh ordinary general meeting of this Company was held on the 22nd inst., at Winchester House, Old Broad-street, under the presidency of Sir John Pender, K.C.M.G., M.P.

The ACTING SECRETARY (Mr. J. Cambrook) read the notice calling the meeting, and afterwards the minutes of the last meeting, which were confirmed by the present meeting, and signed by the Chairman.

The CHAIRMAN: Gentlemen, you have had the report in your hands for some days, and I presume you will take it as read; but before asking you to approve it, I shall make a few remarks, as usual, on the present position of the Company's affairs. Our revenue for the year 1891 amounted to £60,214, as against the takings for 1890 of £68,377, showing a decrease of £8,163. There is a decrease in the Cape joint-purse traffic and the traffic with the French stations; but this is nearly counterbalanced by the increase in traffic with Portuguese and British stations and with South America and local traffic. The principal cause of the reduction in our revenue is the serious depreciation of the Portuguese currency. As will be seen from the accounts, there has been a total loss on exchange of £7,011, nearly the whole of which is due to the loss on remittances between Portugal and England. This matter is receiving the serious consideration of your Directors, and negotiations are pending with a view to a satisfactory settlement. We have been endeavouring to obtain the consent of the Portuguese Government to raise our rate of collection on the West Coast, and the suggestion has been favourably received. Should the matter be formally sanctioned it will to a certain extent minimise the loss on exchange. Fortunately, the money collected in Portuguese currency on the coast has been used for general expenses at the various stations, and the Company has thus been saved a further loss of £2,700, which would have been incurred had the money been remitted to London. The total working expenses for 1891 amounted to £20,883, against £21,685, or a decrease of £802. Several of the items show an increase and others a decrease, the principal decrease being under the heading of working expenses at stations, which are less than last year by £394. Repairs to cables amounted to £2,213, against in 1890 £4,788, or a decrease of £2,575. The balance available for dividend and reserve fund is 12,639, against £17,570, or a decrease of £4,931. It is proposed, therefore, to pay a final dividend of only 2½ per cent., making, with the interim dividend already paid, a total distribution of 4 per cent. for the year, and to carry the balance of £3,395 to the general reserve fund, which now amounts to £30,693. The real question, gentlemen, at the present moment is that of exchange; I cannot hold out very much hope of Portuguese finances improving greatly, but I think that by raising our rates we may be saved from the very serious loss which we are now sustaining. There is another feature in our business which I should mention—namely, that there has been general depression over Africa. People at the Cape are now passing through a phase of depression; but there is such vitality in the country that I have no hesitation myself in coming to the conclusion that brighter days will come again for the Cape, and that with these brighter days we shall have increased traffic, and consequently increased revenue. While the report is not very satisfactory, it is not very unsatisfactory; and taking the ups and downs which occur in the beginning of a telegraph system—which has more or less to be nursed and developed—I think our prospects are upon the whole very favourable indeed. We do not possess the healthiest stations at which to work this system of telegraphy, and, therefore, we have to be very careful in seeing that our staff at the different stations are well looked after. We give them comfortable homes, and do all that we can to ameliorate the conditions of the climate for them; and we feel satisfied that in doing that we are not only benefiting the interests of the Company generally, but also securing for ourselves a class of operators better than we could obtain if their life was left uncertain. With these remarks I beg to move the following resolution:—

"*That the report and accounts for the year ended December 31, 1891, submitted to this meeting, be and they are hereby received and adopted; and that a dividend be now declared, payable on and after this day, of 5s. per share, free of income tax, making, with the dividend already paid, a total distribution for the year of 4 per cent.*"

Sir HENRY C. MANCE, C.I.E., M.Inst.C.E., seconded the motion which was carried unanimously.

The Managing Director (Sir JAMES ANDERSON): I have much pleasure in proposing the following resolution:—

"*That Sir John Pender, K.C.M.G., M.P., and Robert K. Gray, Esq., be, and they are hereby, re-elected Directors of this Company.*"

Sir HENRY MANCE seconded the motion, which was unanimously adopted.

The CHAIRMAN: I am very much obliged to you, gentlemen, for this further evidence of your confidence in me, and I hope I shall be able to show you that it is not misplaced.

Mr. EAST then proposed the re-election of Messrs. Deloitte, Dever, Griffiths and Co. as auditors for the current year, at a remuneration of 50 guineas per annum.

Mr. KENNETH ANDERSON seconded the motion.

The CHAIRMAN put the resolution, and having declared it carried, said: I may mention that Mr. Robert Gray would have been here to-day, but he has a brother who unfortunately is now ill with fever in Brazil; and, like the kind brother he is, he has gone off post haste to visit his relative in what I hope will prove only a temporary illness. I am sure you will all sympathise with him, as we do.

Mr. CUNLIFFE OWEN proposed a vote of thanks to the Chairman and Directors for their able conduct of the Company's affairs. He thought that they might also congratulate the Chairman on his recent parliamentary success; for, apart altogether from politics, they could rejoice at the knowledge that their interests would now be watched over in Parliament by a very able representative.

Digitized by Google

Mr. EAST seconded the motion, which was unanimously agreed to.

The CHAIRMAN: I thank you very much on behalf of my colleagues and myself. We are all very much interested, as you know, in the maintenance of this great Empire. Our submarine telegraph companies have done something to bind the Empire together; and, even as an old man, I thought it was my duty to come forward—although some might think it foolish at my time of life—and assist in keeping together that which we have all worked so hard to build up.

The proceedings then terminated.

Globe Telegraph and Trust Company (Limited).

The nineteenth ordinary general meeting of this Company was held on Tuesday at Winchester House, Old Broad-street, under the presidency of Sir John Pender, K.C.M.G., M.P.

The ACTING SECRETARY (Mr. John Cambrook) read the notice convening the meeting, and the minutes of the last ordinary general meeting, which were confirmed.

The CHAIRMAN: Gentlemen, you have had the report in your hands for some days, and I presume you will take it as read; but before asking you to approve of it, I must give you the reasons for the small difference which has taken place in our dividend this half year. As you are aware, we are a Trust Company. We receive dividends from the different companies whose stocks we hold, and we pay out all the money we receive; and our dividend is more or less guided by the prosperity of other companies. Our receipts for the year ended July 18, 1892, show a decrease, as compared with 1891, after payment of expenses, of £9,455. This is to be accounted for from the fact that we have received £2,184 less on our Anglo-American investment; £3,823 less from the Brazilian Submarine Company, and no dividend from the German-Norwegian Company. We have also received somewhat smaller dividends from the West African and the Western and Brazilian Company—together amounting to about £1,000 less this year. Our accounts show, however, that although our revenue for the present year is £9,455 less than last year, the sum we are able to divide is only £7,697 less, owing to the larger balance brought forward in 1891. We have, then, gentlemen, to recommend to-day a dividend of 4⅞ per cent. for the present year. Last year we were able to recommend a dividend of 5¼ per cent. That is to say, we propose now to pay you 9d. less than last year, owing, as has been said, to our having £7,700 less to divide on account of the smaller returns on some of our investments. Our preference and ordinary shares, taken in like quantities, show a return of £5. 8s. 9d. per cent. The money re-invested in the West Coast Company so far has given us no return, but the prospects of dividend from this source are very promising. There is a line now being constructed across the Andes, which will bring the Brazilian Submarine into communication with the Pacific Coast, and we then expect to see a considerable increase of traffic, not only for the Western and Brazilian Company, but also for the West Coast Line. The Brazilian Submarine Company have given us £4,000 less than they did last year. That Company is building up their reserve fund, and we hope they will soon return to their former dividend for the reason I have stated. The present dividend which we receive from that Company shows a return on our investment of over 7 per cent. With regard to the Anglo-American and the Direct Companies, the former pay us 2s. 8d. per cent. less this year. At the last general meeting the prospect was held out of improvement in the dividends paid by these companies, and it was said that reference would be made to them this year. Anyone who reads the papers from day to day will know that there is at the present moment very considerable depression prevailing. Trade is unhinged, and, as you know, we live by trade; but I cannot for a moment believe that this state of things is going to continue very long, and I hope that when better trade prospects come round, there will be better dividends, and we shall get back to our old position as regards these companies. With respect to the Eastern and Extension Companies, we have a large amount of capital invested in them. They show good returns, their yield to us being over 6½ per cent. taken together. Our American Cable shares show a return of 5¾ per cent., and our Western Union shares pay us £5. 17s. 5d. per cent., and have improved in value. Our holdings in the Western and Brazilian and West African Companies have given us 1 per cent. less on each class of shares for the present year as compared with last year, having paid us this year 4 per cent. compared with 5 per cent. last year. We have to announce the decease of our late Secretary, Mr. Payton, who was a good, useful, and confidential servant during a large period of the existence of the Company. He died the other day, and about the same time we also lost one of our Directors, Mr. Ford. We have expressed in our report our regret at losing the services of such a valuable Director. I have very little to say further. The dividend that we are paying you now is smaller than that which we gave you last year, but I have told you the reasons why it is smaller, and I have also given you my belief that with the general growth of telegraphy our dividend will improve; and telegraphy must grow, for it cannot stand still. Our investments in the different companies are large and important, and I think we may say without any hesitation that they are of a very sound and promising nature, and that with good trade we shall have improved dividends. With bad trade we have to take our chance, but our reduction this time is not serious, and it is one which I strongly believe will very soon be recovered. With these remarks I beg to move the following resolution:—

"*That the report and accounts for the year ended July 18, 1892, submitted to this meeting be, and they are hereby, received and adopted, and that a dividend be now declared, payable on and after this day, of 3s. per share on the Preference Shares, less income tax, and of 3s. 9d. per share on the Ordinary Shares (income tax having already been deducted), making, with previous payments, a total dividend for the year of 6 per cent. on the Preference Shares, less income tax, and of 4⅞ per cent. net on the Ordinary Shares.*"

The MARQUIS OF TWEEDDALE seconded the motion.

The resolution was unanimously adopted without discussion.

The MARQUIS OF TWEEDDALE then proposed the re-election of Sir John Pender, K.C.M.G., M.P., as a Director of the Company. He was sure that he need scarcely say a word in support of the resolution. Sir John Pender had been Chairman of the Company from the first, and had presided over their deliberations with eminent ability and success, and he trusted that the shareholders would show their appreciation of the able manner in which he had looked after their interests by giving the resolution their hearty support.

Sir H. D. GOOCH, Bart., seconded the motion, which was unanimously adopted.

The CHAIRMAN, in reply, thanked the shareholders for the unanimous way in which they had re-elected him. He regretted, as he liked to see a large meeting, that their meetings were growing less; but he could only assume, when he looked at the numbers present and remembered that there were 9,000 shareholders in the Company, that while the meetings were growing less, the confidence of the shareholders in their Directors was growing more. The work of the Board was important in its way. They had to watch what other companies were doing. Some of the Directors were largely interested in those companies; and he must say that in their dealings with them he always asked himself what would be the effect on the Globe Company of any given matter affecting their interests. When, for instance, he heard of the alteration the other day in the tariff of the Western and Brazilian Company, he considered how far the reduction would affect the Globe; and it had affected them a little more than he liked. A reduction from 5¼ per cent. to 4⅞ per cent. was not large, but he liked to go forward; and it would be for them to find out whether, by putting a spur into some of the other companies, they could not get back the little they had lost. He again thanked them for re-electing him, and he assured them that it would be his endeavour to increase still further the confidence of the shareholders in their Directors. He afterwards proposed the re-election of Sir James Anderson, and expressed the hope that that gentleman would try and think of some economies, or of something else, which would restore to the shareholders the small loss of dividend sustained by them on the present occasion.

Mr. JAMES PENDER seconded the motion, which was unanimously adopted.

Sir JAMES ANDERSON, in acknowledging the vote, observed that the fact that the Company referred to had paid a lower dividend was not due to the Directors. If a rival company started and lowered the tariff, what could the other Company do?

On the motion of Mr. T. H. HODGSON, seconded by Mr. W. WILD JONES, the auditors, Mr. John G. Griffiths, F.C.A., and Mr. William Griffith, B.A., were re-elected.

Mr. GRIFFITH, in reply, referred to the admirable way in which the books of the Company were kept, and assured them that all their securities were safe, as he had had ocular demonstration of the fact. He afterwards proposed a vote of thanks to the Chairman and Directors. They were most fortunate in being presided over by a gentleman so well versed in telegraphy and so well known throughout the world, and Sir John Pender was ably supported by men of great reputation and of considerable influence.

The motion was seconded and unanimously carried.

The CHAIRMAN, in reply, stated that all the Directors were deeply interested in the concern, and they aimed at performing their duties in such a way as to enable the auditors to make such a declaration as that made by Mr. Griffith that day. They took care that their relations with other companies were right and that the securities in their strong box were sound and secure. They were pleased to find that the shareholders recognised the responsible position occupied by the Board.

The meeting then separated.

United River Plate Telephone Company (Limited).

The sixth annual ordinary general meeting of the Company was held at Winchester House, 50, Old Broad-street, on Tuesday last; Mr. J. Irving Courtenay presiding.

The SECRETARY (Mr. Robert Herring) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN said: Gentlemen, in moving the adoption of the Directors' report and the balance-sheet I must first point out what an extremely critical period this Company, in common with all other companies in the River Plate, has had to pass through. It has been a crisis that has tested the stability of the soundest undertakings, and no company could stand such a prolonged ordeal unless it was intrinsically sound. Though it may be considered rash to attempt a forecast, still I incline to the opinion that matters (both financial and political) in the River Plate have seen their worst. It would be premature to say that those who are interested in the Argentine Republic are, to use a common expression, "out of the wood;" yet we cannot but hope that the marked improvement in River Plate affairs, which has taken place in the last few months, will continue. We all look forward with confidence to the new Government which will come into power in October next, and that the measures of economy already shadowed forth, aided by careful and prudent administration, will, in time, lift that undoubtedly rich country out of its present unfortunate condition. I would call your special attention to the important fact that the general business in Argentina is steadily improving and confidence is increasing. The recent fall in the gold premium at

Digitized by Google

this time of the year should be assisted by the coming harvest. I will now go through the figures in the profit and loss account and balance sheet, and offer such observations and explanations as may seem to be necessary and desirable. The gross income from the River Plate for the period under review was £98,699. 8s., against £106,259. 19s. 8d. in the previous year. This difference is to some extent caused by a falling off in our subscribers between March 31, 1891, and March 31, 1892; but I may say it is mainly due to our writing off over £5,000 for subscriptions which our Buenos Ayres managers have considered is the most prudent course to pursue; but some of these may yet be recovered. Notwithstanding the economies that have been effected, our expenses in the River Plate have slightly increased. Roughly speaking, there is under this head an apparent increase for the year of £2,000. This is the increase at par of exchange, assuming the paper dollar to be worth 4s.; but to get at the actual sterling increase we must deduct the loss on exchange, which amounts to nearly 75 per cent., thus leaving us a sterling increase of a little over £500 only. We have continuously urged upon our representatives in the River Plate the necessity for carrying out all economies they could consistently with an efficient service, and we believe that they have to the best of their judgment given effect to our wishes; but I would remind you that when I addressed you last year I indicated that some increase in the expenses was to be expected. The principal cause for this is the augmented cost of materials and other necessaries requisite for the carrying on of the ordinary business of the Company. Now, as I have opened necessarily this vital question of the loss on exchange, you will see by referring to the profit and loss account that this loss for the year ending March 31st last is £31,741. 0s. 8d., an amount nearly representing 11 per cent. on the Company's paid-up share capital. You will remember that we had quite a discussion last year upon this same subject; still, I should like again to make you all understand how this exchange figure is arrived at. You will notice that the gross receipts amounted to, say, £98,700, and the whole of our expenditure in the River Plate was in round figures £58,600, thus leaving a profit in paper dollars, the par value of which is £40,100. We are compelled to remit this profit home to pay debenture interest and other expenses in sterling, and in so doing we lose on exchange £31,700, which leaves us a balance when received in London of £8,400 to meet these expenses. In the London expenses we have made a considerable reduction. They stand at £1,838. 2s. 5d., against £2,732. 14s. 9d. for the previous year. Referring to the statement in the Directors' report that since March last the business of the Company has improved in sympathy with the better condition of affairs in the Argentine Republic, and that therefore we think the working for the current year will be much more satisfactory than has been the result of the last year, I will now give you shortly the reasons why we entertain this belief. Firstly, we have a substantial increase in the number of subscribers; then the gold premium has fallen from an average of 280 per cent., to, say, 223 per cent, and I may remind you that during the year it went as high as 365 per cent.; again, it is important to note that there is no proportionate increase in the working expenses on account of the additional number of subscribers, and they have been added to our list at a minimum expense so far as capital outlay is concerned. The shareholders will notice that the capital outlay for the year has been extremely small—£1,003. 18s.—but you must not infer from the smallness of this outlay and the absence of any further addition to the depreciation and renewal fund (which now stands at £9,000) that our plant has not been kept up to its usual high state of efficiency. Our managers in Buenos Ayres and Rosario write us that the whole of it is in first-class condition, and that our service continues to give every satisfaction. We have spent a considerable sum at Buenos Ayres which is charged to revenue, for building new structures, putting up posts, trunk and other lines; and at Rosario, in consequence of the introduction of the electric light, special appliances have been provided to guard against any damage resulting from contacts. We are very much indebted to our representatives in the River Plate, Messrs. Fells and Krabbé, and also to our efficient managers, Messrs. Chappell and Parker, for the very excellent manner in which they have protected the interests of the Company during the exceptionally trying period of the past two years. Some of the shareholders may wish for further information, which, if in our power, we shall be happy to furnish. I now beg to move: —

"*That the report and accounts submitted to the meeting, be, and they are hereby, received and adopted by the Company.*"

Mr. FRANK W. JONES seconded the motion.

Mr. LAWRENCE said that if he gathered the remarks of the Chairman rightly, £40,000 odd was remitted home and produced only £8,400 sterling. This surely must be owing to the unfortunate time at which the money was sent home.

The CHAIRMAN replied that the money is sent home at fixed intervals.

Mr. LAWRENCE asked for information concerning an item in the balance-sheet of nearly £30,000 for conversion of debentures and issue of stock. He would further like to ask whether nothing could be done to increase their receipts in Argentina by way of raising the charges to their customers? It was rather hard to supply telephonic communication in Buenos Ayres at the expense of the English shareholder.

A SHAREHOLDER asked what were the shares of the Province of Buenos Ayres Telephone Company?

The CHAIRMAN: This item has been fully explained at previous meetings. It resulted from our having to convert 7 per cent. debentures at a high premium to 5 per cent. debenture stock. They certainly had power to raise their charges to their customers; but there was a limit beyond which they could not go, and that limit they had reached the last time the charges were increased. The shares in the Province of Buenos Ayres Company were taken in lieu of a bad debt, and were fairly valued at the amount appearing in the balance-sheet. That Company's business was improving.

The motion was then put and carried unanimously.

The CHAIRMAN next proposed the re election of Messrs. George Cooper and Alfred Le Rossignol to their seats at the Board.

The motion was duly seconded by Mr. Billeter and agreed to.

The Company's auditors, Messrs. Cooper Brothers and Co., on the motion of Mr. R. E. BATEMAN, seconded by Mr. J. R. BAILLIE, having been reappointed,

Mr. LAWRENCE proposed a vote of thanks to the Chairman and Directors, which Mr. COURTENAY acknowledged; and the proceedings terminated.

City and South London Railway Company.

The following is the report of the Directors, to be submitted to the half-yearly ordinary general meeting of the Company, to be held at Winchester House, Old Broad-street, E.C., on Friday next, August 5th, at 3 o'clock p.m.: —

The receipts during the half-year from all sources amounted to £21,520. 4s. 8d., and the cost of working for that period to £15,097. 13s. 2d., leaving a profit of £6,422. 11s. 6d. Inclusive of the balance brought forward from last year, the net revenue account shows a total of £7 348. 19s. 9d. After providing the debenture interest, amounting to £4,317. 7s. 4d., there remains a balance available for dividend of £3,031. 12s. 5d., out of which your Directors recommend that the full dividend of 5 per cent. per annum be paid on the Perpetual Preference Shares, and they further recommend that a dividend at the rate of ½ per cent. per annum be paid on the ordinary shares, leaving a balance of £183. 2s. 2d. to be carried forward to next account.

The number of passengers carried by the railway during the six months, exclusive of season ticket holders, was 2,813,162, showing an increase over the corresponding period last year of 400,819.

The steady decrease in the expenditure alluded to in previous reports has been satisfactorily maintained, notwithstanding a considerable further increase in the amount paid for rates and taxes.

The rolling stock and plant have been efficiently maintained and are in good working order. The fourth generating engine and dynamo are erected and ready for use. Arrangements have recently been made by which the public are allowed to view the generating station on payment of a small charge, and this privilege is being availed of to a considerable extent.

During the past Session a joint committee of the two Houses of Parliament was appointed to consider and report upon the best method of dealing with the various electric and cable railway schemes in the metropolis proposed to be sanctioned by Parliament. They reported strongly in favour of electricity as a motive power, and made some valuable suggestions for the extension of railways of this character. The successful working of this line had no doubt much influence in inducing the committee to make so favourable a report.

Owing to the Dissolution of Parliament the Bill promoted by this Company for the extension to Islington and other purposes could not be proceeded with further than the Second Reading in the House of Commons. Your Directors therefore decided to take advantage of the resolution passed by both Houses by which all private Bills are carried over to next Session, when they will be proceeded with at their present stage.

The urgent need of additional siding accommodation at Stockwell Station to meet the requirements of growing traffic renders it desirable that this work should no longer be delayed. To meet this expenditure it will be necessary to issue some additional preference shares. A resolution to that effect will be submitted at the special meeting.

Your Directors being of opinion that the time has now arrived when the present terminable Debenture Mortgage Bonds should be converted into Perpetual Debenture Stock, propose to ask the shareholders for authority to carry this out; and a resolution will be submitted at the special meeting for the creation and issue of Debenture Stock to the extent of the authorised borrowing powers of the Company. It is hoped that a considerable saving in the interest charges will be effected by this operation.

Your Directors have to announce with great regret the death of Major Kitson, who has been one of the auditors since the commencement of the railway. Notice has been received from a large shareholder of his intention to propose Mr. James Lorimer Oliver to fill the vacancy thus created.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES DIRECTORY AND HANDBOOK, 1892, pages 308-322, *&c., &c.*]

AMERICAN INSULATED WIRE COMPANY (LIMITED).—This Company was registered on the 21st inst., with a capital of £75,000, in £5 shares. The objects are to apply for, purchase or otherwise acquire any British or foreign patents, brevets d'invention, licences, concessions, &c., conferring an exclusive or non-exclusive or limited right to use any inventions capable of being used in the manufacture of wire, wire ropes and cables for electric purposes; to use, work, exercise, develop, sell, grant licences in respect of or otherwise turn to account any such British or foreign patents, and to carry on in the United Kingdom or America or elsewhere the businesses of manufacturers of and dealers in wire, wire ropes, and cables of all kinds, founders, machine makers, mechanical and electrical engineers, electricians, suppliers of electricity for the purposes of light, heat, motive power, or otherwise, and manufacturers of and dealers in all apparatus required for

Digitized by Google

er capable of being used in connection with the generation, distribution, supply, accumulation, and employment of electricity. The subscribers (with one share each) are:—Charles G. T. Neumann, Forster-square, Bradford; J. B. Atherton, Rainhill; William M. Brigg, Hawkstone, Keighley; Herman Neumann, 13, Claremont, Bradford; J. Atherton, Huyton; Hugh M. Brigg, Hawkstone, Keighley; Frank J. Leslie, 15, Union-court, Liverpool.

ANDREW BARCLAY, SONS AND CO. (LIMITED).—This Company has been formed, with a capital of £15,000, to carry out agreements with Andrew Barclay, Son, and Co., engineers, Kilmarnock; Thomas Steven, ironfounder, Glasgow; and Joseph Reid, iron merchant, Glasgow; to carry on the business of engineers, ironfounders, boiler-makers, locomotive engine makers, &c., in continuation and extension of the present business of Andrew Barclay, Sons, and Co.

REGENT GOLD EXTRACTING COMPANY (LIMITED).—This Company has been formed, with a capital of £3,000, in £1 shares, to acquire the patents relating to the extraction of metals from ore granted to John E. Chister, to obtain and work mines, ores, and minerals, to operate on ores and minerals, and obtain gold and other metals therefrom. The first subscribers include J. T. Bottomley, 13, University-gardens, Glasgow, and William F. King, electrical engineer, Edinburgh.

ROOTS' PETROLEUM MOTOR SYNDICATE (LIMITED).—This Company was registered on the 22nd inst., with a capital of £2,000, in £1 shares. The objects are to acquire from James D. Roots an invention in respect of which letters patent have from time to time been granted for the United Kingdom and the Isle of Man, and also certain rights acquired conferring protection in France, Belgium, Germany, Austria, Italy, Spain, and the United States of America, and to develop and turn to account the same.

CHELSEA ELECTRICITY SUPPLY COMPANY (LIMITED).—The annual return of the above-named Company, made up to May 26th, was filed on the 20th inst. The Company was registered on November 18, 1884, with a capital of £100,500, divided into 20,000 ordinary shares of £5 each and 500 founders' shares of £1 each. At the time of making up 9,277 ordinary and 500 founders' shares had been taken up, of which the founders' shares had been issued as fully paid, and of which 5,666 ordinary shares had been issued in payment of contracts for plant supplied and erected. Upon the remaining 3,611 ordinary the full amount had been called, and all calls (£18,055) paid.

WESTERN COUNTIES AND SOUTH WALES TELEPHONE COMPANY.—The annual return of this Company, now in voluntary liquidation, on account of sale of business to National Telephone Company, made up to June 22nd, was filed on the 22nd inst. The Company was registered on December 17, 1884, with a capital of £400,000, divided into 20,000 preference shares of £5 each, and 300,000 ordinary shares of £1 each. At the time of making up all the preference and 281,197 ordinary shares had been taken up, of which 3,400 preference and 281,197 ordinary shares had been issued as fully paid. Upon the remaining 16,600 preference shares the full amount had been called, and the calls paid (including £10 which had been paid on 20 forfeited shares) amounted to £83,010.

CITY NOTES, &c.

CALLS DUE.—*Aug. 2nd:* 15s. (final) on 60,000 Ten per Cent. Preference Shares of ELMORE'S FRENCH PATENT COPPER DEPOSITING COMPANY (LIMITED). *Aug. 20th:* £25 per cent. (final) on £10,000 Five per Cent. First Mortgage Debentures of the EXETER ELECTRIC LIGHT COMPANY (LIMITED). *Aug. 31st:* £1 on 45,000 £5 shares of the ISLINGTON AND GENERAL ELECTRIC SUPPLY (LIMITED).

CENTRAL AND SOUTH AMERICAN COMPANY.—This Company has declared a quarterly dividend of 1¾ per cent. The Company has a surplus of about $297,517, and now has 7,100 miles of cable between Galveston, Texas, and Buenos Ayres.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended July 24th were £788, as against £686 for the corresponding period of last year, being an increase of £102. The total receipts for half-year amount to £3,049, against £2,785 in the corresponding period of 1891, being an increase of £264. The Directors' report will be found in another column.

DIRECT SPANISH TELEGRAPH COMPANY.—The Directors recommend dividends at the rate of 10 per cent. per annum on the preference shares, and 4 per cent. per annum (free of income-tax) on the ordinary shares, for the half-year ended June 30th.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company notify that the coupons on their Five per Cent. Debentures, due the 2nd prox., will be paid on and after that date at the banking house of Messrs. Glyn, Mills, Currie and Co., 67, Lombard-street, E.C. Coupons should be left at the bank three clear days for examination.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—This Company announce the payment, by warrants on the 2nd prox., of interest for the half year ending the 31st July, on their Four per Cent. Mortgage Debentures. The transfer books will be closed from the 28th inst. to 2nd August, both days inclusive.

ELECTRICAL COAL-CUTTING CONTRACT CORPORATION.—We are informed that letters of allotment in this Corporation have been posted. The prospectus was privately issued.

ELMORE'S PATENT COPPER DEPOSITING COMPANY (LIMITED).—The Stock Exchange Committee have ordered the additional shares No. 70,001 to 82,395 to be quoted in the Official List.

INTERNATIONAL ELEKTRICITATS GESELLSCHAFT (VIENNA).—At the second general meeting, recently held, it was announced that a profit of £17,694 had resulted from the working of the past year.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—At a special general meeting recently held it was decided to rescind the resolution passed in February, to issue £75,000 debenture stock, and instead to issue £125,000 debentures.

MEXICAN TELEGRAPH COMPANY.—Advices from Mexico, dated July 9th, report that the receipts of this Company for the three months ended June 30th were $82,731, and the operating charges $17,500, leaving a balance of $65,231. A dividend of 2½ per cent. for the quarter is declared, which absorbs $47,815, leaving a balance of $17,416, which, added to the surplus after payment of the April dividend, gives a total surplus in hand of $264,180. The Chairman of the Company stated that over 45 per cent. of the Company's business is derived from connection with the Central and South American Telegraph Company. The latter company intends, it is stated, to duplicate the cable between Salina Cruz, on the west coast of Mexico, and Chorrillos, in Peru, at a cost estimated not to exceed $1,500,000. The Mexican Telegraph Company contracts to pay the Company $20,000 per year for three years from completion of the duplicate cable. English contractors will perform the work.

NATIONAL TELEPHONE COMPANY (LIMITED).—Application has been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to a further issue of £56,477 Four and a-Half per Cent. Debenture Stock of this Company.

NEW TELEPHONE COMPANY (LIMITED).—The prospectus is issued, and will be found elsewhere in our columns, of the New Telephone Company (Limited), with a nominal capital of £750,000, divided into 74,700 ordinary shares of £10 each, and 3,000 founders' shares of £1 each; the latter are not entitled to dividend until after £7 per cent. is paid on the ordinary shares. The present issue is for the balance of 73,200 shares, of which the National Telephone Company subscribe for one-third (the largest number allowed by the Stock Exchange rules). The issue is made by Messrs. N. M. Rothschild and Sons, and on the £10 shares the following amounts are payable—viz., £1 on application, £1 on allotment, £2 three months after allotment, and the balance (in amounts not to exceed £2) as required, with intervals of not less than four months between each call. As will be seen the Board of Directors includes no less than four gentlemen associated with the National Telephone Company, and we are pleased to see that the threatened opposition to the existing Company takes the form of a working arrangement, from which we think the telephoning public should benefit. There is nothing to interfere with the prosperity of the New Company under the altered conditions, unless it be a difficulty in obtaining the 10,000 subscribers which the Directors consider essential to the success of the undertaking. It remains to be seen whether the National Company have failed in the past to obtain a large proportion of the would be telephoning public as subscribers to their system. The agreement between the New Company and the National Company is in the nature of a working arrangement, by which the subscribers to the New Company will be able to communicate through both systems, and *vice versâ*; and one of the chief objects of the two companies will be (the prospectus states) to work in harmony with the new policy adopted by Sir James Fergusson, M.P., as representing Her Majesty's Government. Intending subscribers to the new Company will have the advantage of the double-wire (metallic circuit) system; and all substantial improvements which experience has proved to be essential to the proper conduct of the telephone system in London will be adopted by the new company, which, as our readers are aware, has already as a going concern the Manchester and Bolton exchanges. The necessary outlay for 10,000 subscribers in London, and upwards of that number in the Provinces, have been carefully prepared and considered by Mr. A. R. Bennett, the chief engineer and general manager of the new Company, whose figures have been checked and approved by Prof. S. P. Thompson and Prof. A. B. W. Kennedy. From these estimates it is calculated that the £750,000 capital will suffice for the introduction of the various improvements in the telephone service. The subscription list opened this day (Friday) and closes at or before four o'clock on the same day.

NEWCASTLE AND DISTRICT ELECTRIC LIGHTING COMPANY (LIMITED).—The Directors last week declared an interim dividend for the half-year ended June 30th, at the rate of 5 per cent. per annum, which is the same as last year.

SOCIETE FRANCAISE DES TELEGRAPHES SOUS-MARINS.—The report submitted to the shareholders at the recent annual general meeting showed that the total receipts during 1891 were fr.1,514,499.32, and the expenses fr.818,057.89, leaving a profit of fr 696,441.13. The traffic and subsidy receipts were fr.882,375, an increase of fr.308,763 over those of 1890. A dividend of fr.22.91 per share was declared, and fr.167,056 were carried forward. The Directors stated that obstacles had arisen to the proposal to connect their cable with that of the Société Française du Télégraphie de Paris à New York; but a difficulty which had arisen with the Haytian Government respecting a land line had been removed, and the Company had obtained a 40 years' concession and the exclusive right to land submarine cables.

SOCIETE GENERALE DES TELEPHONES.—A dividend of 20fr. per share has been declared for 1891.

Digitized by Google

TELEPHONE COMPANY OF AUSTRIA (LIMITED).—The ninth ordinary general meeting of this Company, which was announced to be held yesterday afternoon, had to be adjourned *sine die*, owing to the absence of a quorum.

VENEZUELA TELEPHONE AND ELECTRICAL APPLIANCES COMPANY (LIMITED).—Coupon No. 4 of the Five per Cent. First Mortgage Debentures, due July 31st, will be paid from that date upon presentation to the Consolidated Bank, 52, Threadneedle-street, E.C., or at the banking house of Messrs. Westendorp and Co., Amsterdam.

WEST AFRICAN TELEGRAPH COMPANY (LIMITED).—Notice is given that 103 £100 Five per Cent. Mortgage Debentures of this Company were drawn on Friday for repayment at par on September 1st at the National Bank of Scotland (Limited), Nicholas-lane, Lombard-street, E.C. Other particulars will be found in our advertisement columns.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended July 24, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,948.

WIENER ELEKTRICITATS GESELLSCHAFT.—This Company is increasing its capital to £300,000.

WIENER PRIVAT TELEGRAFEN GESELLSCHAFT.—There was a profit on last year's working of £17,708, and a dividend has been declared of 8 per cent. The business is about to be taken over by the Government.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 742.—Vol. XXIX. FRIDAY, AUGUST 5, 1892. PRICE SIXPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

The sixty-second meeting of the British Association was opened on Wednesday last by a lengthy address on the "Geological History of the World," by Sir Archibald Geikie; and the sectional meetings were in full swing yesterday, when Prof. Schuster delivered his presidential address in Section A, and Prof. Unwin in Section G dealt with the history of the steam-engine and the distribution of power. Prof. Schuster's address was of a less practical, though of a more generally interesting character than Prof. Unwin's; solar physics, electric discharges in gases, magnetic theories and educational problems being touched on in succession. Prof. George Forbes read a Paper in Section G on "The Application of Destructors to the Electric Lighting of Edinburgh;" and in Section B, Prof. Crum-Brown read a Paper on "Electrolytic Synthesis."

Three courses are generally open to those upon whom devolves the duty of delivering presidential addresses before scientific societies: they may either review the progress of a particular branch of knowledge during the last fifty years; or, if specialists, they may confine themselves to a description of the work in which they themselves are engaged; or they may discuss some more general but definite subject. We have had rather too many *résumés* of late, and though they may interest the general public, they must be very well done to be attractive to those who take an intelligent interest in scientific matters. The pure specialist is, no doubt, well advised in sticking to his own hobby on these as well as on other occasions; but it would perhaps be well if both presidential addresses and more of the Papers read before the Sections dealt with wider subjects, instead of being based, as they too frequently are, on scrappy notes which the authors would hesitate to present to any other scientific society.

In a Paper "On Transformers," the first portion of which we print in the present issue, Herr Dolivo-Dobrowolsky refers to the loss of power in iron cores due to hysteresis. This well-known engineer states that, as regards the dependence of the core losses on the intensity of the magnetism, the result of his experience is to closely confirm the law recently given in these columns by Mr. Steinmetz, viz., that the core losses are proportional to the 1·6 power of the density of the lines of force. He, however, makes the important remark that the actual amount of hysteresis waste in ordinary transformers is considerably greater than Ewing's numbers would indicate. From two years' tests made on a great number of samples of sheet iron, he finds that, for good medium iron, Ewing's figures should, in general practice, be multiplied by 1·6 or 1·7. The hysteresis losses occurring in transformers are so much greater than any others, that the correctness of this statement is an important question. Ewing's numbers, it is true, were not obtained with alternating currents, but they have been reinvestigated by Messrs. Evershed and Vignoles, and also by Mr. Steinmetz. The values found by these gentlemen were in all cases slightly higher than those of Prof. Ewing; but the differences obtained were small. An increase of 70 per cent., such as Herr Dobrowolsky finds, seems unlikely; and although the iron is said to have been well laminated, we are inclined to attribute much of the extra loss to eddy currents.

In discussing the relative merits of the various forms of magnetic circuit used in transformers Herr Dobrowolsky acknowledges the importance of Mr. Swinburne's work, and, although not endorsing all his conclusions, agrees with him in several important points. The old idea that the iron circuit should be massive and free from joints is shown to be misleading, long thin cores, which allow plenty of room for the copper, being preferable. Also, instead of attempting to save copper by enclosing it as far as possible with iron, the aim should rather be to save iron by surrounding it with copper. In fact, the idea of reducing the copper losses is delusive, not only because the greater losses occurring in the iron renders this saving unimportant, but also because the regulation for different loads so secured is apparent and not real, since the drop of volts caused by the resistance of the leads is disregarded. Herr Dobrowolsky does not advocate the open magnetic circuit, but shows that it is possible by attention to these principles to design transformers of the closed-circuit type with an all-day efficiency of over 90 per cent. This excellent result is obtained by allowing from 5 to 6 per cent. of the output at full load to be lost in the copper, an amount which is in excess of the usual English practice. The recent tests of Westinghouse transformers by Dr. Hopkinson show, however, that it is possible to design closed-circuit transformers with a higher all-day efficiency than 90 per cent., with a smaller loss in the copper, and thus without any serious drop of volts due to the resistance of the coils.

The correctness of the objections raised by Messrs. Kelly and Steinmetz to the claims made in favour of the polyphase motor depends more upon the nature of the assumptions made than upon the truth of the reasoning. It will be seen, from the abstract of the discussion which we print elsewhere, that it is quite possible for two sine currents, differing in phase by a quarter of a period, to supply energy at a constant rate; and Herr Dobrowolsky's conclusions in this respect appear to require modification. But the practical question is whether the rotating field obtained with three-phase currents is more constant in strength than when two-phase currents are used. The arguments of Mr. Steinmetz would be more applicable if each coil traversed by the current consisted of a single turn, instead of several, occupying an appreciable portion of the circumference, and if the coils were wound on a drum armature instead of on a Gramme ring. When wound as usual in the latter fashion, the magnetomotive forces due to the differently phased currents in the coils add up in the same way as the electromotive forces in the coils wound round the semicircumference of a Gramme ring. In a dynamo the greater the number of commutator sections, the more constant is the voltage of the machine, and similarly in a polyphase motor the greater the number of phases the more constant is the strength of the rotating magnetic field. While the brush of a dynamo is moving over the bar of a commutator the position of the coils, with reference to the external circuit, is unaltered electrically, and the connection between them is not altered continuously, but by intermittent changes. Similarly while the direction of the resultant field in a polyphase motor is sweeping over one of the coils, the currents in the two parts of this coil are oppositely directed as regards the magnetic circuit, and do not produce the requisite magnetising force to keep the field constant.

The shape of alternate-current curves has formed the subject of several researches, notably of some by Messrs. Ryan and Merritt, who succeeded in showing that these curves are made up by combining a simple sine curve with others whose periods are odd multiples of the period of the principal wave. These harmonics have generally been attributed to hysteresis; but Prof. Rowland, in a brief note on transformers contributed to the current issue of the *Philosophical Magazine*, shows that they may be perfectly accounted for as a consequence of the fact that the permeability of the iron varies with the strength of the magnetising force. It is also shown that the effect of hysteresis is equivalent to increasing the resistance of the coils, and that the importance of the harmonics becomes greater as the magnetism of the core increases. Prof. Rowland's conclusion that the harmonics are due simply to variable permeability and do not depend on hysteresis seems, however, to need confirmation, since the line of argument used appears as well adapted to show that the effects are due to hysteresis as to changes in permeability.

The French are a logical people, and some of them are beginning to ask why trading and commercial telegrams are charged at higher rates than press telegrams. Journalism—or rather the conduct of journals—is a trade, pursued with the same objects as every other business, and therefore entitled to no special privilege not enjoyed by the trading community. We quite agree with the reasoning, but our conclusion would be different. Remove the inequality by all means, but begin with the press. The only excuse that we can see for its special privileges is the same as that which accounts for our giving a cabman fifty per cent. more than his fare—because he would bully us frightfully if we didn't. As to the argument that the national revenue would be benefited by an extension of press rates to business firms, one may reasonably ask why not also to private families? To leave them outside the privileged circle would be to make them pay for the deficiency created by special tariffs; and to include them in that circle would be to extinguish privilege altogether. Probably the French Deputies will see the matter in that light before they have done with it.

Free-Trade in glow-lamps, like free-trade in other commodities, will not prove an unalloyed blessing if we may judge from the state of things which obtains in Germany at the present moment. Our German correspondent reports this week that the price of the best make of 16-c.p. lamps has recently been reduced from 1s. 6d. to 1s. This sudden move has apparently exasperated the smaller manufacturers, and they are now bewildering the unfortunate consumer with a shower of pamphlets which fill his mind with visions of 1½-watt lamps, and make no mention of life or of constancy of candle-power, points with respect to which the leading makers have something to say in a warning circular which they have found it necessary to issue. In this country glow-lamps are discreetly sold without any guarantee as to life, constancy or efficiency; but when the free-trade era commences, rival makers will in all probability be driven by stress of competition from this nonchalant attitude, and a plentiful crop of litigation may be expected to follow.

Eccles.—The Local Board has decided to apply for an Electric Lighting Order.

Hammersmith Vestry.—This Vestry has decided to apply for an Electric Lighting Order.

Brussels.—The final settlement of the electric lighting question is deferred for another three months.

Canadian Patent Law.—The Dominion Senate has passed a Bill to amend the Patent Act, extending the life of a patent from 15 to 18 years, and doing away with the necessity of models.

Owens College, Manchester.—A special course has been arranged at this College on the technical applications of electricity. For further particulars see our advertisement columns.

Electric Launches.—The Westminster Yachting Association have organised a daily excursion by road and river. A coach runs from the Grand Hotel to Kingston, where passengers embark on the electric launch "Omicron," for Chertsey.

Chicago Exhibition.—With regard to the rumour which has been pretty generally circulated that the Chicago Exhibition Executive was bankrupt, it is stated that the fact is the Exhibition has now $2,500,000 cash in bank, and about a million more in sight.

Telegraphy in West Africa.—The German Postal authorities are said to be making inquiries of several telegraph engineers whether they would be willing to set up a system of telegraph lines in West Africa, particularly in the German dependencies of the Cameroons and Togo.

Digitized by Google

Copper.—According to Messrs. R. Merton and Co. the stock of copper in England and France and afloat thereto amounted at the end of July to 59,738 tons, as against 57,782 tons at the end of July, 1891. The average price of Chili bars was £44. 17s. 6d. during July last, and £52 during the same month of 1891.

Personal.—Mr. H. B. Bourne has been appointed electrical engineer to the International Okonite Company as regards their contract for laying mains in Manchester.—The Corporation of Blackpool have selected Mr. John Hesketh, of the Newcastle-on-Tyne Electric Supply Company, for the appointment of electrical engineer to that borough.

Bedford.—At a special meeting of the Town Council, held on Monday last week, a communication from the Bedford Electric Light Company was considered. After a lengthy discussion it was formally resolved that the Board of Trade should be informed that negotiations were now pending with a view to the transfer of the powers of the Order of 1890, and that the application of the Bedford Electric Light and other companies should be considered.

Appointments in Cable Companies.—The following appointments have been made:—Mr. G. R. Neilson, to be assistant secretary of the Eastern Telegraph Company (Limited); Mr. Sidney Collet, to be secretary of the Globe Telegraph and Trust Company (Limited); Mr. John Cambrook, secretary of the West African Telegraph Company (Limited); and the Hon. A. G. Brodrick, secretary of the Submarine Cables Trust. These changes are consequent upon the death of Mr. William Payton, late secretary of the three last named companies.

International Exhibitors' Association.—We have received a pamphlet relating to this Association, which has been formed in New York by merchants who expect to exhibit at Chicago. The Association, it is stated, has been formed for obtaining privileges and effecting economies. It is expected that by this co-operative work exhibitors will be able to make a considerable saving. The Association proposes to assist its members both in getting their goods to Chicago, installing them, and looking after them. The head office of the association is in the Stewart Building, New York, and the membership fee is $25.

Earth Currents.—The following extract from a letter from Aden station, dated July 21, 1892, will be read with interest in connection with the remarks on the same subject which will be found elsewhere in the present issue:—

"On Saturday, 16th instant, there were indications of a strong magnetic storm. It was felt on all circuits, and caused the recorder syphons to go off paper from one side to the other, somewhat interfering with the traffic. It lasted from about 6:30 p.m. until 9 p.m. We were afraid of delaying the work, otherwise it would have been interesting to have taken more observations. As it was we observed Suez No. 2 on the galvanometer for a few minutes (that cable being clear at the time), and found the maximum earth-current equal to 52 volts negative. It was probably more on the other cables. On Zanzibar section it was especially marked."

Taunton.—On Monday last week a special meeting of the Town Council was held for the purpose of considering the proposal to purchase the electric light works. The Electric Lighting Committee presented a report in which they recommended that the amount necessary be raised by borrowing for a period of 50 years, or such other period as the Local Government Board would grant. The amount which it is proposed to expend is £14,000. Of this £9,300 will be devoted to the purchase of the works, while £1,900 will be expended in the substitution of underground for overhead wires; £1,000 of the total will be set apart as working capital. The Council by eleven votes to three adopted this report.

Electrical Communication with Lighthouses.—At a recent meeting of the Cardiff Health and Port Sanitary Committee a letter was read from Mr. J. Gavey, superintending engineer of the Post Office Telegraph Department in South Wales, stating that the department were about to make certain experiments with a view of ascertaining how far it may be possible to establish electrical communication with outlying lighthouses, without the necessity for laying special submarine cables, and stating that it was desirable such experiments should be made, if possible, between the mainland near Lavernock and the Flat Holms. In order to facilitate this public work, he asked permission for himself and his staff to land at the Flat Holms, and lay temporary wires across the island with a view of thoroughly testing the feasibility of the proposal. It was unanimously agreed to grant the permission asked.

The New Telephone Company.—The following extracts from a leading article which appeared in the *Economist* of July 30th will secure the attention to which the remarks of this financial journal are always entitled:—

"The promoters of the New Telephone Company, who during the past week invited subscriptions for £488,000, part of an authorised capital of £750,000, have displayed a considerable amount of prudent forethought in securing the services of Messrs. N. M. Rothschild and Sons as their issuing agents; for although the new departures made by that firm in recent years have sometimes seemed to old-fashioned people somewhat venturesome, the reputation of the great financial establishment still stands high among the investing classes of the country. We cannot believe, however, that their reputation will be enhanced by their connection with this telephone company. . . . . The fact that the National Telephone Company is to subscribe for one-third of the capital of the New Company, and has nominated one-half of the Board of the undertaking, including its own president and vice-president, is made the most of in the prospectus; but the arrangement does not seem to us an advantageous one to the New Company, to say nothing of the requirements of the public. . . . It is desirable, of course, that the interchange of means of communication should be made as perfect as possible; but the connection between the two companies is obviously intended to stifle competition, and thus prevent such a lowering of the charges as the public have a right to demand, seeing that the companies are to have a sort of copartnership with the Post Office. . . . . It is indisputable that the telephone service forms part and parcel of the telegraph monopoly owned by the State; and those who are responsible to the public would perform their duties in a very lax manner if they permitted the exaction of charges which must inevitably retard the development of the telephone industry, and thus render the Governmental portion of the business less remunerative than it should be."

Dublin.—On Friday last the report of the Electric Lighting Committee came up for adoption by the Town Council at a special meeting. The following resolution was carried unanimously:—"That the report be adopted with this exception, that the Committee shall not be compelled to enter into any contract with the Messrs. Hammond and Co., but shall have power if they see fit to enter into a contract to run the station and plant and any extension of same for one year with either Messrs. Hammond and Co., or, if they see fit, may undertake and carry out the running of the station themselves, employ workmen, purchase materials, and do all necessary acts in the matter." It was intimated to the meeting that a notice had been received from the contractors, Messrs. Hammond and Co., that they would contest the right of the Corporation to take the contract for twelve months from them and give it to any other firm. The report stated that, owing to some of the electric light customers being in urgent need of current, it was absolutely necessary that the Committee should be given plenary powers with regard to making arrangements for running the station.—It appears from an article by Mr. A. Fahie in the *Health Record* that the Corporation propose to charge 8d. per unit for any quantity up to 100 units, and above that amount 7d. per unit. A minimum of £2 per quarter is proposed, as well as rent for transformer, which varies from 5s. to £2 per quarter, and rent of meter 5s. per quarter.

The Electrical Resistance of the Human Body.—M. Von Frey has applied to the human body Kohlrausch's method of determining the resistance of electrolytes by means of alternating currents and the telephone. Certain modifications were found to be necessary. It was necessary to dispense with the metre measuring wire, since its resistance is so small compared with that of the human body that, in order to hear any sound at all, it is necessary to use induction-currents so strong as to be painful to the subject of experiment. The measuring wire was replaced by a circular groove not completely closed, filled with solution of zinc sulphate, in which the part connecting it with the telephone could be moved round like the hand of a clock. It was further found that platinum electrodes of 10 to 20 square centimetre surface, which Kohlrausch found quite sufficient for measuring the resistance of liquids, are by no means adequate with the human body to produce a cessation of sound in the telephone in any position whatever. It was only when the surface of contact between the metal and the moist hand was increased to several hundred square centimetres that the sound ceased, or, at any rate, there was a very

Digitized by Google

pronounced meniscus. The surface necessary varies with the region of the body. In order uniformly to moisten large surfaces of the body, they were immersed in troughs through which the current was passed by cleanly polished zinc plates. In such conditions the resistance of the body was found to be very small (from hand to hand 3--400 ohms), and, as was to be expected, independent of the induction-currents.

A Novel Application of Storage Batteries to Electric Traction.—A most interesting exhibition of the application of storage batteries for propelling electric cars was given in Dover, N.H., July 12th, says the *Electrical Engineer* of New York. The road is operated by the Union Electric Street Railway Company, power being furnished from the station of the Great Falls Electric Light Company, situated on the Salmon Falls River. The road is full of steep grades, and in one part, about half a mile out of Dover, there is a grade of over nine per cent., which taxes the trolley system to the uttermost at all times, and when the cars are heavily loaded proves too much for it. In the past it has been found necessary to employ horses to aid the electric car in surmounting the grade. The station from which the current is derived is several miles away, so that there is a heavy fall of potential when the car is drawing on the current when ascending the hill. It was at last decided to try Bradbury-Stone storage batteries as an auxiliary. Accordingly in a small outhouse in the vicinity, 238 cells were installed, giving a total voltage of from 530 to 540 volts. The trolley wire on the hill is now cut off from the remainder of the system, and wires leading from the storage battery are connected to it, so that as soon as the trolley comes in contact with this section, which is about 300ft. long, the current is all taken from the batteries. The experiment has worked most successfully. On July 12th a very severe test was made. The special car containing about fifty people was hitched on to one of the regular trip cars, also well loaded, the one car pulling the other, and both ascended the hill without a hitch, the battery registering about 510 to 520 volts, and the current consumed being from 100 to 180 amperes.

Press Rates for Commercial Telegrams.—A number of traders and manufacturers recently petitioned the French Chamber of Deputies in favour of granting to commercial and industrial telegraphic despatches the reduced tariff applicable to press telegrams. M. Leconte, deputy, charged to report on the matter, has approved of the conclusions of the petition. He contends that journalism may be classed as a kind of trade. Political, industrial, and commercial communications which now serve to maintain and cover the expenses of the press, have an incontestable final object: to use the advantages that the circulation of journals offers for realising pecuniary benefits. Is that not also the object of all traders? If this similarity be admitted, why should that be refused to the one which is accorded to the other? Why should preference be given to journalism to the detriment of other commercial or industrial branches? If it be objected that the lowering of the telegraph rates would lead to a fall in the receipts of the Post-office for the exchange of correspondence, the reporter says it is easy to reply that the receipts from telegrams go, like those of the Post-office, into the coffers of the State. And it may be added that the rates for telegraphic correspondence, being incontestably higher than the rates for letters, it is to be presumed that the receipts from telegrams would be much augmented, and that consequently the State treasury, instead of being lightened, would be better filled. The reporter believes that the reform would result in a real benefit to the public treasury, whilst the adoption of the principle of the petition could not but favour the development of commercial and industrial transactions. The petition has been remitted, with a favourable opinion, to the Minister of Commerce.

The Proposed International Electrical Exhibition at Milan.—Preliminary steps for the organisation of an International Electrical Exhibition to be held at Milan in the spring of 1894, have been taken by a group of gentlemen connected with the professional and industrial interests involved. As it is necessary to decide upon the size of the buildings required for the Exhibition, the Committee have addressed forms for preliminary application for space to persons interested. No formal engagement need be entered into. All that is wanted is an assurance of intention to exhibit, and an approximate estimate of the space required. The Exhibition is an entirely private enterprise, and it has therefore been decided that the space occupied should be paid for by the exhibitors, at a moderate rate. It is considered that this contribution towards expenses may be fairly asked for, in view of the advantages, both direct and indirect, which exhibitors will secure themselves by promoting the success of the Exhibition. It is proposed to inaugurate a series of tests, and besides the usual medals a sum of money will, it is said, be put at the disposal of the jury, in order that a large premium may be allotted to the exhibit embodying the most important improvement brought forward at the Exhibition connected with the transmission of electrical energy to a distance and its subdivision and distribution for industrial purposes. The preliminary forms should be returned before August 15th, to the Exhibition Committee, 9, Via Unione, Milano. The Committee consists of Angelo Bertini, electrical engineer; Francesco Grassi, Professor of Physics at the Societá d'Incoraggiamento d'Arti e Mestieri; Palamede Guzzi, engineer; Cesare Saldini, Professor at the Istituto Tecnico Superiore; Augusto Stucchi, manufacturer.

Aluminium v. Copper.—In a recent number of the *Electrical World* Mr. A. Saunders Morris discusses the *pros* and *cons* of the employment of aluminium in electrical construction. Aluminium, he points out, is about one-third the weight of copper. The specific resistance is, however, almost twice as great as copper. The weight for an equivalent resistance will therefore be ·555 that of copper, or cost of aluminium $= \frac{\text{cost of copper}}{\cdot 555}$. The area of an aluminium wire of the same resistance as a copper wire having to be greater, the insulation for an aluminium wire would weigh about 36 per cent. more. The average saving in weight by using aluminium in place of copper for insulated wire, as estimated from manufacturers' tables, is 33 per cent. for the lowest grade of insulation, 22 per cent. for the next grade, and 18 per cent. for the best. If aluminium is used instead of copper in lead-covered cables, the weight, instead of being decreased, is increased. The disadvantages in the use of aluminium for electric conductors are: First, increased cross-section and its attendant circumstances, increased surface to be covered with insulation, increased surface exposed to wind, and increased danger from accumulations of snow and sleet, as well as the objectionable appearance of larger wires than at present used. Second, the great difficulty of soldering, although this objection is largely decreased by the use of mechanical joints not requiring solder. Third, the decreased tensile strength, which, however, is partly neutralised by the fact that the cross-section is nearly doubled. Its sole advantage is the decrease in weight; but the strength of poles is ample to support the weight of copper wire were it not for the side strains to which they are subjected, and which, in general, would be greater for aluminium than for copper. Mr. Morris next deals with the use of aluminium in the construction of transformers, dynamos, motors, &c.; and after balancing the decrease in the weight of the conductor circuit against the increase in weight of the magnetic circuit, &c., works out that the actual saving in weight is about 2 per cent.; but the volume being increased, the weight of the containing case would have to be increased, which would make the aluminium-wound transformer somewhat heavier than one wound with copper. If, again, aluminium were used instead of copper in a direct-current generator, the armature, to have the same ohmic resistance and the same air gap, would have to be considerably larger. This would in turn require larger fields, and these would have to be somewhat increased in general dimensions to accommodate the increased section of wire, so that in all probability what would be saved in weight by using aluminium would be lost on account of the greater weight of iron necessary for structural reasons; indeed, it would be difficult to use aluminium without changing the design materially, and probably sacrificing efficiency. The inability to use solder becomes a far more serious difficulty in machine construction than in line work. From the facts it would seem that, however great the usefulness of aluminium in general, its substitution for copper in the field of electricity is limited, even if its present price were materially reduced.

LORD RAYLEIGH.

We publish this week a steel-plate portrait of Lord Rayleigh, Sec. R.S. Lord Rayleigh is the son of the second Baron Rayleigh, of Terling Place, Witham, Essex. He was born in 1842. He received his school education under Mr. Warner at Torquay, and in 1861 entered as a Fellow Commoner at Trinity College, Cambridge. From that time on, his mathematical powers began to show themselves, and in 1865 he graduated in the Mathematical Tripos as Senior Wrangler. He was also awarded the first Smith's Prize. In 1866 he obtained a Fellowship at Trinity, which he held till his marriage in 1871. He became a Fellow of the Royal Society in 1873. At present he is one of the Secretaries of the Society, and Professor of Natural Philosophy in the Royal Institution.

Lord Rayleigh's work in Physics has been of a very varied character; he has covered a wide range, and he has handled each subject with a thoroughness and clearness which have enabled him to add greatly to our knowledge in nearly every branch of the science. In attempting to give a very brief sketch of his work we may conveniently divide his life into three portions: the first lasting till 1879, when he succeeded Maxwell as Professor of Experimental Physics in Cambridge; the second, comprising the five years during which he held the Professorship; and the third, continuing from 1884 to the present time.

In the first period Lord Rayleigh's researches were mainly mathematical. The *Philosophical Magazine* for 1871 and 1872 contains a series of most important optical Papers, "On the Light from the Sky, its Polarisation and Colour," "On the Scattering of Light by Small Particles," "On the Reflection of Light from Transparent Matter," "On Double Refraction," and "On the Reflection and Refraction of Light by Intensely Opaque Matter." The results of these may be briefly summed up as follows:—The blue colour of the sky is caused by the scattering of light of the shorter wave lengths by the finer particles suspended in the air. Lord Rayleigh showed that the colour of this light and its polarisation could be satisfactorily accounted for on the undulatory theory; and, further, that to explain the observations, Fresnel's hypothesis as to the nature of the vibrations and their relation to the plane of polarisation, and not that of Neumann and MacCullagh, must be assumed. In the two Papers on Reflection and Refraction he calls attention to Green's work, bringing out clearly the points in which it fails to account for the facts, as well as its transcendent merits when compared with any other theory which had been proposed. The unsatisfactory character of Cauchy's theory of metallic reflection as shown by the results of Jamin's experiments is also discussed. In fact, these Papers, together with Sir G. G. Stokes's "Report on Double Refraction" in the B.A. Report for 1862, and his Paper on Diffraction, sum up the whole of what was then known of the dynamics of Optics. Other optical questions of a practical character are discussed in a communication to *Nature*, "On Some Experiments on Colour in 1871," which was followed by further work ten years later; and in Papers "On the Manufacture and Theory of Diffraction Gratings" (*Phil. Mag.*, 1871). Another series of Papers in the *Phil. Mag.* for 1873 deals with various theorems relating to vibrating systems in general; and the same subject was discussed in Papers read before the London Mathematical Society. This and kindred work culminated in the "Treatise on the Theory of Sound," the first volume of which was published in 1877, while the second followed in the next year. In connection with this the words of Prof. von Helmholtz, when reviewing in *Nature* the first volume, may be quoted:—"The author will merit in the highest degree the thanks of all who study Physics and Mathematics, if he continue it in the same manner in which he has begun it in the first volume."

A Paper on "Resonance" published in the *Philosophical Transactions* for 1871 needs special notice here, for in it Lord Rayleigh first developed a method of calculating approximately the resistance of conductors of any given form which has many and wide applications. Among experimental Papers of this period we may refer to two "On Some Electromagnetic Phenomena in Connection with the Dynamical Theory," and "On Electromagnetic Experiments" (*Phil. Mag.*, Vols. XXXVIII. and XXXIX.), in which some of the consequences of self-induction are discussed, and the effects of rapidly alternating currents in producing magnetism considered. In a Paper "On Waves" (*Phil. Mag.*, 1876) the theory of Scott Russell's Solitary Wave is developed. The Paper concludes with some interesting results on oscillations in cylindrical vessels. The *Proceedings* of the London Mathematical Society about this date contain many other Papers by Lord Rayleigh.

Clark Maxwell died in 1879, and shortly afterwards Lord Rayleigh was invited by an influential body of Cambridge men to be a candidate for the vacant chair. He consented, and was at once unanimously appointed. Maxwell's work had been to build the Cavendish Laboratory and to equip it with apparatus. The whole was the most generous gift of the Chancellor of the University, the late Duke of Devonshire. This work of preparation was barely concluded in 1879. It fell to Lord Rayleigh to organise the Laboratory in its twofold aspect. There was need for a school of experimental physicists, who might bring to bear on physical problems the skilled powers acquired by the training for the Mathematical Tripos; there was need also for teaching of a more elementary character to large classes of students who could gain by actual contact with apparatus, and by making measurements with their own hands, a far deeper insight into fundamental natural laws, the clear comprehension of which is in itself of the highest educational value, and which in many instances are of great practical importance to the student. Lord Rayleigh set himself to satisfy both these needs. Under his active supervision a system of practical instruction in Experimental Physics was devised. The number of students attending the classes grew rapidly from year to year. At first there were some five or six; in 1884, when Lord Rayleigh ceased to be Professor, there were seventy, while during the present academical year that number has grown to about one hundred and forty.

But Lord Rayleigh's own research work while Professor of Physics at Cambridge is of more interest to the readers of *The Electrician*. The experimental part of this is to be found mainly in the well-known quarto volume entitled "Electrical Measurements: Rayleigh," though we must not forget some optical and other Papers which will be mentioned shortly. The writings of Thomson (Lord Kelvin) and the experiments of Maxwell, Fleeming Jenkin, Matthiessen and Hockin had established the C.-G.-S. system of absolute electrical measurement. The experience of even a few years had shown the importance of a uniform system of measurements, and the need for accurate standards—an importance and a need which each succeeding year has only intensified. That we in England possess such standards of resistance, current and electromotive force as the result of English research, is due to Lord Rayleigh.

The B.A. unit was intended to have a resistance of 10^9 C.-G.-S. units; but the work of Joule, of Rowland, and of Kohlrausch had thrown doubt on this result. Cambridge was of all places the spot where it could best be repeated; for the apparatus originally used by Maxwell and his partners in King's College, where their measurements were affected by the iron of the passing steamers on the Thames, and the resistance coils which Matthiessen and Hockin had constructed to represent the results of the experiments, were in the Cavendish Laboratory. Dr. Fleming's recent intercomparison of these resistances had shown that it was highly improbable that they had changed, and so the first step was to set up the old Spinning Coil apparatus and repeat the experiments. This was done with the aid of Dr. Schuster. In the course of the reduction, one error made by the Committee was discovered. The value of the self-induction, which in this method comes in as an important correction, had been seriously under estimated, but this alone will not explain the discrepancy which the experiments proved to exist between the B.A. unit and the ohm; the result of the work gave as the value of the B.A. unit 0·9893 ohm. But the experiments had shown that the old apparatus was capable of great improvement in many of its details, and so a new coil was constructed and the whole repeated. Lord Rayleigh has a marvellous knack of seeing

Digitized by Google

just the weak points of a method; and while, like Fresnel, who accomplished much of his work on diffraction with apparatus made by a country blacksmith, he can achieve results of the highest importance with materials of the simplest character, yet where refinement and accurate workmanship are really necessary for his purpose, these are employed with no grudging hand. Hence in this case the accuracy attained was considerably greater than before. The value actually found was $0{\cdot}9865 \times 10^9$.

The various methods of determining the standard of resistance were discussed by Lord Rayleigh in a Paper in the *Phil. Mag.* for November, 1882. As a result of his discussion he concludes that Lorentz's method is the best of all. Accordingly, he undertook, in conjunction with his sister-in-law, Mrs. H. Sidgwick, a determination by that method; the result of this, published in 1883, was 0·9868 ohm. Another series of experiments made at the Cavendish Laboratory in 1882 by Mr. Glazebrook, using Kirchhoff's method, gives the value 0·9867 ohm, while the mean of the seven most reliable experiments up to the present date is 0·98653. Various considerations had led electricians to the conclusion that the results of these experiments could be best expressed by determining the length of the column of mercury of a given cross-section 1 sq. mm., which has a resistance of 1 ohm; among other things, the evidence for the permanence of coils of platinum silver was not so strong as it is now. Thus it was necessary to find the specific resistance of mercury. This had been determined by Matthiessen and by Dr. W. Siemens, but their values differed by 0·8 per cent. Lord Rayleigh and Mrs. Sidgwick undertook this task, and their experiments are published in the *Phil. Trans.* for 1883. The value found for the resistance in B.A. units of a column of mercury, 100 cm. long, 1 sq. mm. in section was 0·9541, which is rather greater than the mean, 0·95354, of all the most reliable experiments.

But standards of current and of electromotive force are at least as urgently needed as standards of resistance; and the question of obtaining these was next dealt with in the Papers "On the Electro-Chemical Equivalent of Silver," and "On the Absolute Electromotive Force of Clark Cells" (*Phil. Trans.*, Part II., 1884). The problem differs from that of the standard of resistance in an important particular. A tube of mercury or a piece of wire has under given physical conditions a definite resistance. It is not possible to produce a concrete unit current, though we can arrange apparatus in which a certain effect is produced when the unit current is passing. The primary question to settle was, what effect of a current is to be taken. The fundamental property of a current on which the definition of unit current turns is its power of exerting magnetic force. The property investigated by Lord Rayleigh as a means of measuring a current was the electro-chemical deposition of silver; the object, then, of the research was to connect the two, to determine how much silver is deposited per second from a solution of nitrate of silver by a current which under certain circumstances exerts unit magnetic force on a magnet pole. Lord Rayleigh found that a current of one ampere deposits 0·0011179 gramme of silver per second; the result obtained by Kohlrausch is 0·0011183. The Paper contains details for carrying out the measurements necessary—these have been explained recently in *The Electrician* by Mr. Searle. It also deals with the electromotive force of various forms of cells, and shows that when proper precautions are taken in setting up the cell and preparing the materials, the electromotive force of Clark's cell is very constant, and is equal to 1·4345 volts at 15°C. Thus by these series of investigations Lord Rayleigh determined while at Cambridge the three fundamental units of resistance, current, and electromotive force.

Another piece of experimental electrical work was the measurement of Verdet's constant for bisulphide of carbon, the angle, that is, through which the plane of polarisation of light is rotated when travelling along lines of magnetic force between two points which differ in potential by unity. Suggestions, have from time to time been made for using this rotation as a means of measuring electric currents. Lord Rayleigh's investigations went to show that there is not much hope of success in this direction.

But these years, so fruitful in experimental work, were by no means barren in other respects. A series of Papers, "Investigations in Optics," published in the *Phil. Mag.* for 1879 and 1880, have thrown much light on the behaviour of various optical instruments; and a Paper "On the Electro-Magnetic Theory of Light" (*Phil. Mag.*, June, 1881) contains an application of that theory to the scattering of light by small particles.

In 1882 Lord Rayleigh was President of Section A of the British Association. In his address he discussed to some extent the relation of Mathematics to Experimental Physics, and expressed the wish, which many will re-echo, that he might "see a course of Mathematical instruction arranged with special reference to Physics, within which those whose bent was plainly towards experiment might, more or less completely, confine themselves." Two years later, in 1884, he occupied the Presidential chair at the Montreal meeting, and spoke in hopeful language of the future of applied electricity. He concluded with a tribute to Maxwell, into whose labours he had entered in a special sense, and "to whose influence, in conjunction with that of Thomson and of Helmholtz, is largely due that elimination of unnecessary hypothesis which is one of the distinguishing characteristics of the science of the present day."

Soon after his return from America Lord Rayleigh resigned his Cambridge chair. In 1885 he suceeeded Sir G. G. Stokes as one of the Secretaries of the Royal Society, and a few years later he became Professor of Natural Philosophy in the Royal Institution, in succession to Prof. Tyndall. Papers on a large variety of subjects have continued to flow from his pen; perhaps the most interesting to electricians are a series which appeared in the *Phil. Mag.*, Vols. XXI., XXII., and XXIII. The first of these deals with "The Self-Induction and Resistance of Straight Conductors." Prof Hughes, in his striking address to the Society of Telegraph Engineers, in January, 1886, had called attention to some of the effects due to induction in short pieces of wire. For the complete interpretation of his results, the value of the co-efficient of self-induction of a wire conveying a rapidly alternating current was required. The problem had, with some important limitations, been studied by Maxwell. Lord Rayleigh's work introduced some corrections into Maxwell's formulæ, and considerably extended his results. An experimental investigation of the problems treated by Prof. Hughes is given in the Papers on "The Self-Induction and Resistance of Compound Conductors" (*Phil. Mag.*, Vol. XXII., p. 469). An earlier Paper in the same volume, "Notes on Magnetism," p. 175, deals with some of the questions raised by Ewing's discovery of magnetic hysteresis; while in a third Paper (Vol. XXIII., p. 225), Lord Rayleigh showed that in the case of iron and steel for small magnetising forces, ranging for steel from $\frac{1}{3}$ to $\frac{1}{10000}$, of the earth's horizontal force, the magnetisation is strictly in proportion to the magnetising force; the value of μ for soft iron being about 90.

During the last year and a-half Lord Rayleigh has been a member of the Electrical Standards Committee of the Board of Trade, the outcome of whose work will be, should their report remain unmodified, to legalise, at any rate for the English-speaking countries of the world, his determinations of electrical standards. Space compels us to pass over in the briefest manner many of Lord Rayleigh's other contributions to science. In the article, "Wave Theory," in the "Encyclopædia Britannica," he has summed up in a masterly manner our knowledge of the theory of light; while, in various Papers scattered through the *Phil. Mag.* and elsewhere, he has dealt with individual optical questions of great interest. Chemists owe him a debt for his recent work on the relative densities of oxygen and hydrogen, for which he arrived at the number 15·882 (*Proc. Roy. Soc.*, Vol. L., p. 448), while the results he has attained in his Papers "On the Theory of Surface Tension," and "On the Tension of Water Surfaces, Clean and Contaminated" (*Phil. Mag.*, Vol. XXX., *Proc. Roy. Soc.*, Vol. XLVII.) have a wide bearing in many directions. A special interest attaches to the Paper "On Reflection from Liquid Surfaces in the Neighbourhood of the Polarising Angle" (*Phil. Mag.*, Jan. 1892), for in it Lord Rayleigh showed that light can be

Digitized by Google

completely polarised by reflection from a clean surface; and this is what, according to the electromagnetic theory, should take place. We have thus reason for supposing that in all cases the Jamin effect, as it is called, *i.e.*, the want of complete polarisation, is due to surface-films; and the theory of reflection and refraction is much simplified.

This most inadequate account of Lord Rayleigh's life will, perhaps, suffice to show what he has done to carry on the work begun by Maxwell at the Cavendish Laboratory, and to secure for English Physics that high place in the world's esteem, which, thanks to the genius of Stokes and Kelvin, Maxwell and Rayleigh, it now holds.

ELECTROMAGNETIC THEORY.—XXXIV.

BY OLIVER HEAVISIDE.

(*Continued from page 328.*)

§157. If it be asked why, in the previous analogies, a preference has usually been shown for the representation of magnetic force (or a constant multiple thereof) by velocity, the answer would be, substantially, that it has been done in order to make the magnetic energy be kinetic. Now, it is true that in a perfectly abstract electromagnetic scheme, arranged in duplex form—in which every electric magnitude has its magnetic representative—and, therefore, including a magnetic conduction-current with waste of energy, there would be a perfect balance of evidence as regards the kinetic nature of either the electric or the magnetic energy, when the other is to be potential energy, as of a state of strain in an elastic medium. For, if it were argued from a certain set of relations that the magnetic energy was kinetic, the force of the argument could be at once destroyed by picking out an analogous set of relations tending to show (in the same way as before) that the electric energy was kinetic.

But, as matters actually stand, with an imperfect correspondence between the electric and magnetic sides of the electromagnetic scheme, there seems to be a considerable preponderance of evidence in favour of the kinetic nature of the magnetic energy. We may refer, in particular, to the laws of linear electric circuits, which were shown by Maxwell to be simply deducible by the ordinary equations of motion (generalised) of a dynamical system, on the assumption that magnetic energy is kinetic; there being one degree of freedom for every circuit, and the variables being such that every linear electric current is a (generalised) velocity. In this theory, the dielectric in which the conducting circuits are immersed is regarded as unyielding, so that electric displacement cannot occur in it, and the currents are confined entirely to the conductors.

Now, we could construct a precisely similar theory of conductive magnetic circuits immersed in a medium permitting displacement, but destitute of magnetic inductivity. The circuital flux of magnetic induction in the former case would now be replaced by a similar circuital flux of electric displacement; the former electric currents becoming magnetic currents, and the magnetic energy becoming electric energy. But this electric energy, when expressed in terms of the linear magnetic currents, would possess the property of allowing us to deduce from it the laws of the magnetic circuits, by using the generalised equations of motion, on the assumption that electric energy is kinetic, in a manner resembling Maxwell's deduction of the laws of electric circuits. Therefore, supposing the state of things mentioned to really exist, we might become impressed with the idea that electric energy is kinetic; just as, at present, it seems hardly possible to avoid entertaining the idea of the kinetic nature of the magnetic energy.

We do not, however, need to go to generalised dynamics to arrive at this probable conclusion. It is sufficient to start with a sound general knowledge of dynamical facts and principles, not necessarily mathematical, but such as may be acquired in practical experience by an intelligent and thoughtful mind, involving clear ideas about inertia, momentum, force, and work, and how they are practically connected (the Act of Parliament notwithstanding). On then proceeding to the experimental study of electrokinetics, including the phenomena of self-induction in particular, the dynamical ideas will be found to come in quite naturally. Lastly, the generalised theoretical dynamics will serve to clinch the matter. Although adding little that is novel, it will corroborate former conclusions, and co-ordinate the facts in a compact and systematic manner, suitable to a dynamical science.

On the other hand, there is little that is suggestive of kinetic ideas in electrostatics, whilst there is much that is suggestive of the potential energy of a strained state. This fact, combined with the kinetic suggestiveness of the facts (and the equations embodying them) in which magnetic induction and electric currents are concerned, explains why the association of magnetic with kinetic, and electric with potential energy becomes natural. It is, therefore, somewhat a matter of surprise, as well as rather vexing, to find that in order to extend the last-considered rotational analogy to a conducting dielectric, we must, if we wish to do it simply, give up the comparison of magnetic force with velocity and electric force with torque, and adopt the converse system, making the electric energy be kinetic, and the magnetic energy the potential energy of the rotation.

We can, perhaps most easily see that this plan should be adopted by writing down the two circuital equations of electromagnetism, and then, immediately under them, the corresponding proposed circuital equations of the rotational ether. Thus, taking $\mathbf{H}$ to be velocity, as before, we have, to express the first circuital law in the dielectric and its mechanical companion,

$$\mathbf{g} + \text{curl}\,\mathbf{H} = cp\mathbf{E}, \quad . \quad . \quad . \quad . \quad . \quad (357)$$

$$\mathbf{g}_1 + \text{curl}\,\mathbf{q} = \frac{1}{\nu} p(\tfrac{1}{2}\mathbf{S}). \quad . \quad . \quad . \quad (358)$$

Here the terms in vertical are to be compared. Magnetic force $\mathbf{H}$ becoming velocity $\mathbf{q}$, the electric force $\mathbf{E}$ becomes $\frac{1}{2}\mathbf{S}$, or half the torque; c the permittivity is the compliancy ν^{-1}, and $\mathbf{g}_1$ is a newly-introduced companion to $\mathbf{g}$, which is the source $-\text{curl}\,\mathbf{h}$. It will be interpreted later.

The other circuital equations are

$$\mathbf{f} - \text{curl}\,\mathbf{E} = \mu p\mathbf{H}, \quad . \quad . \quad . \quad . \quad (359)$$

$$\mathbf{f}_1 - \text{curl}\,(\tfrac{1}{2}\mathbf{S}) = \rho p\mathbf{q}. \quad . \quad . \quad . \quad . \quad (360)$$

We now have the additional analogues of inductivity and density, and $\mathbf{f}$, which is the source curl $\mathbf{e}$, with $\mathbf{f}_1$, which is impressed translational force per unit volume.

So far relating to a non-conducting dielectric, and giving an intelligible dynamical analogy, if we wish to extend it to a conducting dielectric, according to Maxwell's scheme (including, of course, a pure conductor which has, or is assumed to have, no permittivity), we require to change cp in the first circuital law (357) to $k + cp$, whilst the second circuital law needs no change. But the right number of (358) needs to be changed to match the modified (357). Thus

$$\mathbf{g} + \text{curl}\,\mathbf{H} = (k + cp)\mathbf{E}, \quad . \quad . \quad . \quad . \quad (361)$$

$$\mathbf{g}_1 + \text{curl}\,\mathbf{q} = (k_1 + \nu^{-1}p)\,(\tfrac{1}{2}\mathbf{S}), \quad . \quad . \quad (362)$$

where k_1 is the new coefficient, to match k. But what is its interpretation in the rotational ether, and how is the latter to be modified to make k_1 as intelligible as the other constants?

Now, since we use rotational elasticity to obtain the potential energy, and we associate the rotation with the electric displacement, it is suggested that rotational friction should be introduced to cause the waste of energy analogous to that of Joule. But if there were frictional resistance proportional to the spin, we should have

$$\mathbf{S} = 2(\nu + \nu_1 p)\,\text{curl}\,\mathbf{G}, \quad . \quad . \quad . \quad . \quad (363)$$

instead of (352), connecting the torque with the rotation. But this will not harmonise at all with (362). We cannot do what we want by rotational friction, but require some special arrangement, whose nature does not appear, in order to interpret (362) intelligibly.

But, by changing the form of the analogy, choosing the electric energy to be kinetic, the extension to a conducting

Digitized by Google

dielectric can be made in a sufficiently obvious manner. Put (360) under (361), thus

$$\mathbf{g} + \operatorname{curl} \mathbf{H} = (k + cp)\mathbf{E}, \quad . \quad . \quad . \quad . \quad (364)$$

$$\mathbf{f}_1 + \operatorname{curl} (-\tfrac{1}{2}\mathbf{S}) = (\rho_1 + \rho p)\mathbf{q}, \quad . \quad . \quad . \quad (365)$$

where we introduce ρ_1 to match k. Also put (358) under (359), to get the other pair, thus

$$\mathbf{f} - \operatorname{curl} \mathbf{E} = \mu p \mathbf{H}, \quad . \quad . \quad . \quad . \quad (366)$$

$$-\mathbf{g}_1 - \operatorname{curl} \mathbf{q} = \frac{1}{\nu} p(-\tfrac{1}{2}\mathbf{S}). \quad . \quad . \quad . \quad (367)$$

We have now a fit, with an intelligible meaning to be given to the new coefficient that brings in waste of energy. For (365), which is compared with the first circuital law, is the translational equation of motion in the rotational ether when there is frictional resistance to translation, expressed by $\rho_1\mathbf{q}$, so that ρ_1 is the frictionality, and $\rho_1\mathbf{q}^2$ the rate of waste.

The correspondences in detail are as follows:—

	$\mathbf{A} = \mathbf{E}/p$	stands	for	$\mathbf{G}$,	(spacial displ.).
(el. force)	$\mathbf{E}$	,,	,,	$\mathbf{q}$,	(velocity).
(permittivity)	c	,,	,,	ρ,	(density).
(el. displ.)	$\mathbf{D}$	,,	,,	$\rho\mathbf{q}$,	(momentum).
(el. energy)	$\frac{1}{2}c\mathbf{E}^2$	,,	,,	$\frac{1}{2}\rho\mathbf{q}^2$,	(kin. energy).
(mag. force)	$\mathbf{H}$	,,	,,	$-\frac{1}{2}\mathbf{S}$,	($-\frac{1}{2}$ torque).
(inductivity)	μ	,,	,,	ν^{-1},	(compliancy).
(induction)	$\mathbf{B}$	,,	,,	$-\frac{1}{2}\nu^{-1}\mathbf{S}$,	
(mag. energy)	$\frac{1}{2}\mu\mathbf{H}^2$	,,	,,	$\frac{1}{2}\nu(\operatorname{curl}\mathbf{G})^2$,	(rotl. energy).
(conductivity)	k	,,	,,	ρ_1,	(frictionality).
(cond. current)	$\mathbf{C} = k\mathbf{E}$	,,	,,	$\rho_1\mathbf{q}$,	
(Joule-heat)	$k\mathbf{E}^2$	,,	,,	$\rho_1\mathbf{q}^2$,	(rate of waste).
(true current)	$\mathbf{C} + p\mathbf{D}$	,,	,,	$(\rho_1 + \rho p)\mathbf{q}$.	

These should be studied in connection with the circuital equations (364), (366), and their matches underneath them, if it be desired to obtain "an intelligent comprehension" of the true nature of the analogy, and to correct any errors that may have crept in.

If we keep away from the sources of energy, there is little difficulty in understanding the analogy in a broad manner. But the sources require special attention before the electromagnetic and rotational analogues are intelligible. We know that activity is the product of two factors a "force" and a "velocity." Newton knew that. In modern dynamics, too, where the velocity is not a primitive velocity, but has a generalised meaning—the time-rate of change of some variable—the corresponding force generalised (not a primitive force) is still such that the product of "force" and "velocity" is activity, or activity per unit volume, &c., according to convenience. In our electromagnetic equations, for instance, $\mathbf{EC}$ and $\mathbf{H}\dot{\mathbf{B}}$ and $\mathbf{E}\dot{\mathbf{D}}$ are activities (per unit volume), and we call $\mathbf{E}$ and $\mathbf{H}$ the "forces" (intensities) and the other factors the fluxes, the corresponding "velocities." Similarly, $\mathbf{eC}$, $\mathbf{e}\dot{\mathbf{D}}$, and $\mathbf{h}\dot{\mathbf{B}}$ are activities (per unit volume understood), where $\mathbf{e}$ and $\mathbf{h}$ are intrinsic, communicating energy to the system.

Now, since the "variables" may be variously chosen in a dynamical system, we need not be surprised if it should sometimes happen that the (generalised) force turns out to be a (primitive) velocity, and the (generalised) velocity to be a (primitive) force. Here is food for the scoffer, for one thing. At any rate, we should be careful not to confound distinct ideas, and remember the meaning of the activity product. Our present rotational analogy furnishes an illustration. We have the equation of activity,

$$\mathbf{e}(\mathbf{C} + \dot{\mathbf{D}}) + \mathbf{h}\dot{\mathbf{B}} = \mathrm{Q} + \dot{\mathrm{U}} + \dot{\mathrm{T}} + \operatorname{div} \mathbf{W}, \quad . \quad (368)$$

where

$$\mathbf{W} = \mathrm{V}(\mathbf{E} - \mathbf{e})(\mathbf{H} - \mathbf{h}). \quad . \quad . \quad (369)$$

$\mathbf{W}$ is the energy-flux, Q the rate of waste, U the electric, and T the magnetic energy per unit volume, whilst the left member represents the rate of supply of energy by the intrinsic sources $\mathbf{e}$ and $\mathbf{h}$, being the sum of their activities.

Now what are the analogues of $\mathbf{e}$ and $\mathbf{h}$? Remember that only their curls appear in the circuital equations and that $\mathbf{f}$ and $\mathbf{g}$ are the sources of disturbances. By inspection of (365), (367), we see that $\mathbf{f}_1$ is the curl of a torque, and $\mathbf{g}_1$ the curl of a velocity, say

$$2\mathbf{f}_1 = \operatorname{curl} \mathbf{S}_0, \qquad \mathbf{g}_1 = -\operatorname{curl} \mathbf{q}_0. \quad . \quad . \quad (370)$$

Then, just as the analogue of $\mathbf{H}$ is $-\frac{1}{2}\mathbf{S}$, the analogue of $\mathbf{h}$ is $-\frac{1}{2}\mathbf{S}_0$. Impressed magnetic force is, therefore, represented by an impressed torque per unit volume, and its activity is

$$(-\tfrac{1}{2}\mathbf{S}_0)\nu^{-1}p(-\tfrac{1}{2}\mathbf{S}), \quad . \quad . \quad . \quad . \quad (371)$$

which is, of course, plain enough. But the other activity is

$$\mathbf{q}_0(\rho_1 + \rho p)\mathbf{q}, \quad . \quad . \quad . \quad . \quad . \quad (372)$$

where $\mathbf{q}_0$ is the analogue of $\mathbf{e}$. Here the supposed "force" has become a velocity, and the "velocity" a force. For the factor of $\mathbf{q}_0$ in (372) is the analogue of electric current-density, and means the (primitive) force per unit volume in the rotational ether, partly employed in increasing momentum, partly working against friction. Of course this perversion is rather extreme.

The rotational analogues of (368), (369) may be readily written down by proper translations in accordance with the above, remembering (370).

Mr. W. Williams, who has recently (Physical Society, 1892) published a very close study of the theory of the "dimensions" of physical magnitudes, on applying his views to the electromagnetic equations and the rotational ether, has arrived at the conclusion that the representation of either $\mathbf{E}$ or $\mathbf{H}$ by velocity leads to the only two systems that are dynamically intelligible. It should be remembered, however, that his conclusion is subject to certain limitations (mentioned in his paper) regarding dimensions, for otherwise the conclusion might seem to be of too absolute a nature, as if one of $\mathbf{E}$ or $\mathbf{H}$ *must* be velocity. In any case, I cannot go further myself at present than to regard the rotational ether as furnishing a good analogy, which may lead later to something better and more comprehensive. The present limitation to small motions (in general) is a serious one, and there are other difficulties.

(To be continued.)

ON THE RATE OF PROPAGATION OF ELECTRO-MAGNETIC OSCILLATIONS IN INSULATING MEDIUMS, AND ON MAXWELL'S RELATION.*

BY R. BLONDLOT.

Considerations of homogeneity lead to an extremely simple relation concerning the propagation of electro magnetic waves in different insulating mediums. If we take an electric oscillator made of an extremely good conducting metal, the waves which it is capable of emitting when it is at work in a certain medium have a length which can only depend on the shape and size of the oscillator on the one hand and of the electrical properties of the medium on the other. Assuming this medium to be an insulator, its electrical properties are defined by a single coefficient, viz., its dielectric constant or specific inductive capacity, K, the magnetic constants of all known dielectrics being sensibly equal to each other. It follows that λ can only be a function of a certain number of lengths defining the shape and size of the oscillator and the coefficient K. On the other hand, the numerical value of K depends on the unit of time chosen,† which may be an arbitrary one. It is impossible, therefore, that the expression λ, which is a length, should contain K; hence *for a given oscillator the length of the waves which it is capable of emitting should be the same whatever the insulating medium in which the experiment takes place.*

I have verified this hypothesis in the case of liquid dielectrics. The electric waves were produced and transmitted by the method which I have described,‡ along two parallel wires of tinned copper eight centimetres apart. A gilded copper resonator, similar to that which I employed to determine the rate of propagation of electric waves, was arranged between the two wires. The portion of the resonator forming the condenser was contained in a glass vessel. The portion of the transmission

* From *Comptes Rendus*, Vol. CXV., p. 225.

† The dimensions of K are $L^{-2}T^2$.

‡ *Comptes Rendus*, Vol. CXIV., p. 283; see also *The Electrician*, Vol. XXVIII., p. 627.

Digitized by Google

wires situated on the far side of the resonator was contained in a wooden trough four metres long. The glass vessel and the trough being empty, I determined the position of the movable bridge for non-sparking. The distance of this bridge from the resonator was therefore one-fourth of the wave length proper to the resonator; there was no necessity to measure this, and I contented myself with marking exactly the position of the bridge. This done the vessel containing the condenser was filled with the liquid chosen. It was ascertained that the wave length became greater (it increased from 14·8 metres to more than 25 metres in an experiment made with essence of turpentine). The trough was then filled with the same liquid, and in determining once more the position of the bridge involving the disappearance of sparking in the resonator, it was ascertained that this position was exactly the same as in the first part of the experiment, when the glass vessel and the trough contained air. The experiment was equally successful with both the dielectrics which I employed, viz, essence of turpentine and castor oil.* The verification of the law was complete.

It may be remarked that acoustics present us with an analogous phenomenon, a sounding tube always emits waves the length of which depends solely upon that of the tube, and is consequently independent of the nature of the atmosphere in which the vibrations are caused to take place.

From the above law I deduce the important consequence which M. Potier has also noticed. Between the capacity C and the coefficient of self-induction L and the period T of my resonator the following relation exists:—

$$T = 2\pi\sqrt{CL},$$

whence multiplying both sides of the equation by V, the rate of propagation of the waves, we have

$$\lambda = 2\pi\sqrt{L} \times \sqrt{C} \times V,$$

and as λ and L are independent of the nature of the dielectric medium the product C V ought also to be so. Hence in passing from air to another dielectric the value of C becomes K times greater, and the value of V should be multiplied by the reciprocal of the index of refraction $\left(\frac{1}{n}\right)$ of the new medium; Hence we ought to have $K \times \frac{1}{n^2} = 1$, or $K = n^2$.

This is the relation arrived at theoretically by Maxwell.

I have thus verified this relation for the two liquids which I employed, and my experiments confirm those of Messrs. L. Arons and H. Rubens, recently published.† Castor oil has a special interest since when we try to deduce from the values of the luminous indices of this substance the index which would correspond to infinite wave length by aid of the dispersion formula of Cauchy, we obtain the number 1·4674, whilst the square root of the dielectric constant is 2·18.‡ Maxwell's relation, therefore, seems in fault, but it is the method of verification which is incorrect. I would remark that my experiments rigorously fulfilled the conditions demanded in order that Maxwell's relation should be applicable, viz., that the values K and n should relate to phenomena of the same period; they offer, moreover, the advantageous circumstance of being independent of all measurements, since they are only based upon the determination of the equality of two lengths.

It must not be thought that the reasoning founded on considerations of homogeneity, which led me to Maxwell's relation, should necessarily be applicable to all dielectrics, and that experimental verifications are superfluous. This reasoning supposes, in fact, that the dielectric properties of the medium are defined by a single dielectric constant. If several coefficients were necessary, the wave length corresponding to a given oscillator could no longer be independent of the medium, and Maxwell's relation might fail. Experiment, therefore, can only ultimately decide the matter.

I am indebted greatly to M. M. Dufour, who has helped in the most kind manner in carrying out these experiments.

* I will explain further on why castor oil possesses particular interest.

COMMUTATORS.—IV.

BY F. M. WEYMOUTH.

(*Concluded from page 335.*)

It is essential with all commutators that they be driven direct from the shaft. Hence we find in Figs. 12 and 14 (see p. 334 of last issue) that the sleeve is keyed to the shaft, while in Figs. 3, 4, 8 and 13 a steel pin is driven into the shaft, as at g, for this purpose. The nuts, whether of gunmetal, wrought iron, or steel, are usually circular, with radial holes or else rectangular notches in the rim, for the use of a tommy to tighten up with. But, as shown in Fig. 12, horizontal holes parallel with the shaft may also be adopted; while two flats, one on each side the nut, for the use of a spanner, is another method.

But now, however, to turn aside from the consideration of the interior construction of different forms of commutators, we may give our attention to some remaining items, which are more or less independent of the interior construction. Thus, we may notice some of the various methods in which the lugs are dealt with, and connection formed with the armature winding.

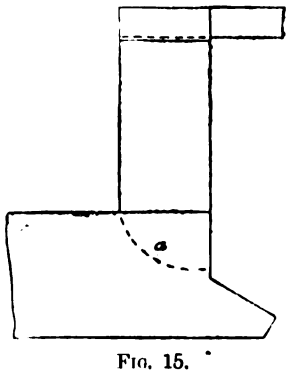

Fig. 15.

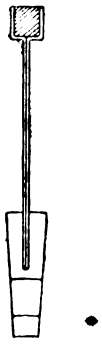

Fig. 16.

As already intimated, the commutator lugs may be either cast in one with the segments, or they may be separate pieces soldered or brazed in. This latter has of necessity to be the method adopted when the segments are of rolled copper, except, perhaps, when, as in cases previously alluded to, the armature is wire wound, and the commutator large in proportion. The lugs when separate are frequently made of two strips of copper rivetted together, opening out into a fork at the outer end to receive the winding end. This is shown herewith, Figs. 15 and 16. The nitch in the segment receiving the inner ends is cut out with a small circular saw, which accounts for the rounded corner a.

Fig. 17.

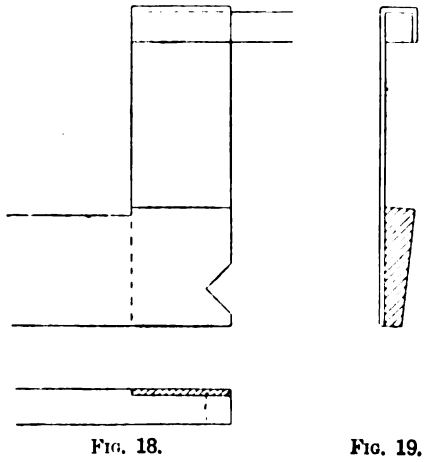

Fig. 18.

Fig. 19.

Figs. 17 to 19 are other variations. Here one strip only is used, bent over at the top as shown, so as nearly to enclose the winding end soldered into it; and the inner end, instead of being received in a nitch, lies in a recess at the side of the segment, which may, however, be cut with a saw the same as the nitch. A very common way, instead of enfolding the

Digitized by Google

winding end when this is a bar, is to make a saw cut in the bar end to receive the outer end of the lug, as shown in Figs. 20 and 21. The lug is then simply a straight strip of copper, received and soldered or otherwise fastened into a saw cut at

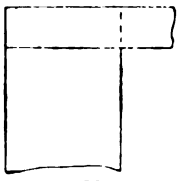

Fig. 20.

Fig. 21.

both ends. A case where rolled segments may be combined with wire winding without the use of additional lugs is illustrated in Figs. 22 and 23 herewith. *Quasi* lugs are formed by turning a groove *d* in the segments.

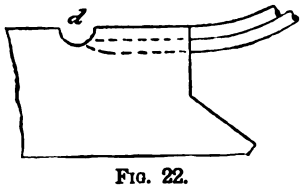

Fig. 22.

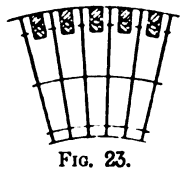

Fig. 23.

Turning our attention now to cast segments, we find a common form in Figs. 24 and 25. Here very short lugs only are necessary, with wire winding, when, as in the previous

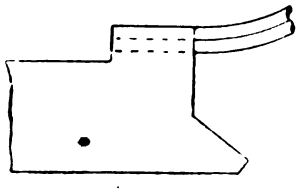

Fig. 24.

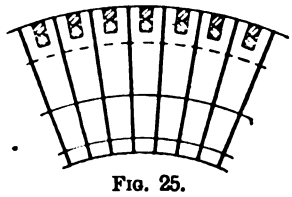

Fig. 25.

figures, the wire can easily be bent down to the smaller diameter of the commutator. In the case, however, of bar-wound armatures for heavy currents, where the bar ends cannot be

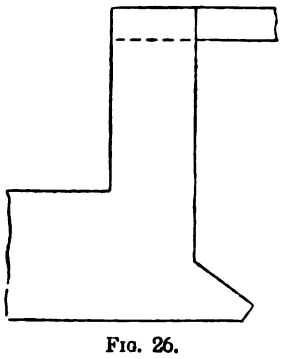

Fig. 26.

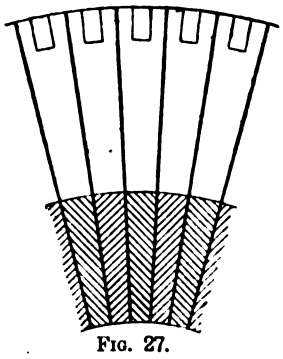

Fig. 27.

brought down, the lugs must then extend to the full diameter of the armature, as illustrated in Figs. 26 and 27. This looks

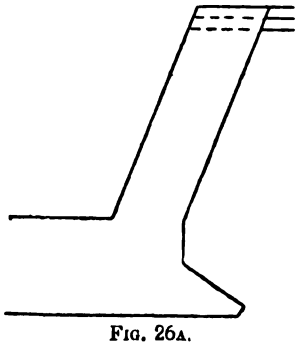

Fig. 26A.

very neat, the lugs being all turned up bright as well as the brush contact surface. Fig. 26A is a variety where the lugs are sloped toward the armature. This has the advantage of allowing more room for the brush-holder, so that the brushes can bear right up to the roots of the lugs. It also practically eliminates the short piece of single conductor bar that passes from the armature end winding to the lugs. For this piece has to carry the *whole* current when in series with the brush, and being only of a size adapted properly to carry but *half* the current, it offers a resistance. Generally, however, this is considered neglible owing to the shortness of the piece; and the bar does not heat as it otherwise might, owing to the fact that it revolves in the open air, and so is kept cool. But another variety

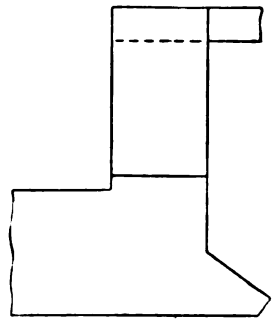

Fig. 28.

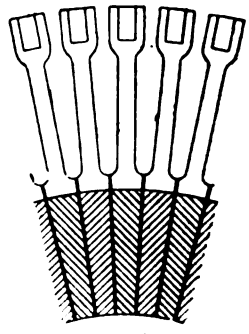

Fig. 29.

of the same thing is shown in Figs. 28 and 29. Here, it will be seen, the lugs, instead of being carried out solid to the outer periphery, are considerably lightened, and open spaces left between them. This latter arrangement, especially when there is much difference between the diameters of the armature and commutator, must be decidedly more economical. For there is less metal and less insulation than in the former, and labour is saved in not having to machine or file up the sides of the lugs. Ventilation, moreover, is completely stopped in Fig. 27, but not in Fig. 29. A good example, however, of the method shown in Figs. 26 and 27 occurs in the case of the two

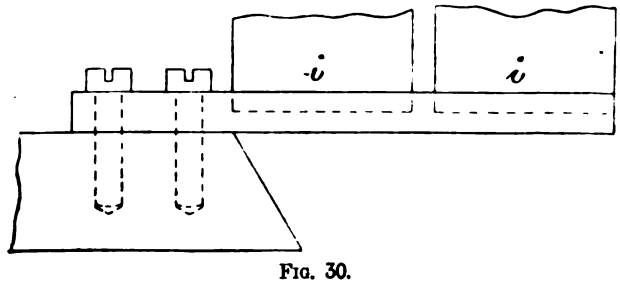

Fig. 30.

commutators of the Elwell-Parker motor generator, or continuous-current transformer, already once alluded to. For here the commutators, especially the high-tension, are abnormally large in diameter. Fig. 30 illustrates a further method of connection, used in the case of the Hopkinson adaptation of the Hefner-Alteneck end winding for drum armatures. Here union is made with the interior ends of the cross connections, instead of to the exterior. Hence a bar, screwed to the segments, and soldered or brazed or otherwise fastened to the ends of the involutes *i i*, is all that is required for the purpose.

EARTH CURRENTS.

The following notes based on reports sent in by cable stations extending from London to Singapore exhibit in a striking way the ubiquity and simultaneity which so frequently characterise earth-current disturbances. It was thought at first that there was evidence to connect this "magnetic storm" with the eruption of Etna, but in looking into the matter it was found that the eruption began about a week before July 16th, although indeed it was very active on that date. It is interesting to note that the Atlantic cables were similarly affected on the date named, and at about the same time.

London.—Earth currents were observed on all the circuits between London on the one hand, and Porthcurnow, Manchester and Liverpool,

Digitized by Google

Glasgow and Paris on the other, between 12 p.m. and 8:30 p.m. on Saturday, the 16th ult. At about 12:40 p.m. every wire was stopped from this cause, the appearance and disappearance being simultaneous on each. Between 4 and 8:30 p.m. the currents were very pronounced, but occurred only at intervals, and not invariably at the same moment on all circuits.

Falmouth.—Some of the traffic was nearly stopped on Spanish lines on July 16th, including the Madrid-Barcelona, Madrid-Bordeaux wires, on account of earth currents, which were very irregular in tension, but mostly of positive sign. On July 17th the earth currents on the Bilbao cable were about four times the normal tension. The London-Falmouth land line was much affected on the 16th ult. and 17th ult., but not on the 18th ult.

Porthcurnow.—No abnormal earth currents were observed on the cables to Spain and Portugal during the week preceding the 18th ; but some interference from this cause on land lines was noticed between 4 and 6 p.m. on the 12th ult., also at intervals between noon and 8 p.m. on the 16th ult., and from midnight to 2 a.m. on the 17th ult.

Gibraltar.—Here there were strong earth current disturbances on the Cadiz and Tangier cables between noon on July 16th and 2:30 a.m. on July 17th.

Marseilles.—On Saturday, the 16th, 7:40 p.m., to Sunday, the 17th, 2:40 a.m., the London and Paris wires were affected by strong earth currents, the Algiers cables being affected at the same time, but less intensely. The Eastern Company's lines to Bona and Malta were not influenced.

Bona.—At Bona earth currents were observed on Friday, July 15th, at 10 p.m. There was a large deflection on the mirror when working through between Marseilles and Malta, stopping positive current coming from Malta, and shifting the spot at Bona. No deflection was observed when working in section ; but at Bona a large condenser of 20 microfarads is used.

Malta.—A strong and variable earth current was experienced on the Zante section on July 16th, between 1 and 1:30 p.m.; also during greater part of the same evening, and again between 9 and 9:30 a.m. on the 17th. Nothing was noticed on the other sections.

Zante.—On Saturday, July 16th, all the sections worked with great difficulty, owing to the excessively strong earth currents, especially on Trieste, Athens, and Syra circuits. All the Italian land lines were affected.

Alexandria.—On Saturday, July 16th, at 5:25 p.m. (Greenwich time), strong earth currents on land-lines and on cables were noticed ; the syphon vibrated to the extent of about a quarter of an inch for a few seconds only, nothing was noticed before or after.

Suez.—On July 16th, at 7:30 p.m. (Cairo time), strong earth currents were present on all the cables to Suakim, Perim and Aden for a short time.

Bombay.—Strong earth currents occurred on the Aden cable at 10:40 p.m. on July 16th, but they did not stop work. The Government lines were affected on the 16th at 2:30 until 8 a.m. on the 17th, and again on that date from 4:30 p.m. to 6 p.m.

Singapore.—There was a slight earthquake at Banjoewangie 1:50 a.m. on July 14th, and the signals on the Sinagapore Banjoewangie cable became feeble at 3 a.m. On Saturday night, July 16th, and on Sunday, July 17th, there were very strong earth currents on all sections to Batavia, Penang and Saigon, which died away on July 18th. A considerable fall of insulation on the Saigon-Hongkong and Shanghai cables was reported.

LEAD ACCUMULATORS FROM A CHEMICAL STANDPOINT.*

BY G. DARRIEUS.

In the introduction the author points out, that although the most generally accepted hypothesis concerning the reactions occurring during discharge in lead batteries is that sulphating takes place at both plates, it is scarcely probable that the same body, SO_3 for example, acts at both electrodes at the same instant. The formation of the same body by electrolysis at each electrode is contrary to Faraday's law, and the theory of double sulphating at both plates appears to have been adopted because it brings Lord Kelvin's law into harmony with the results of experiment.

Physical and Chemical Constitution of the Accumulators before Discharge.

At the commencement of charge the positive plate may be supposed to consist simply of metallic lead, and what happens during charge is in agreement with the laws of electrolysis. The lead is oxidised and acquires a characteristic tint, and if the charge is stopped at the moment when the colour is uniform and gas is given off freely, and the plate is then dipped into a vessel of pure water, a syrupy liquid flows from the bottom of the plate, whilst small bubbles of gas break on its surface. The gas is oxygen, and suggests the presence of some unstable peroxide body which is decomposed by the water. The peroxide body was found to be persulphuric acid, and it was further found that it was always present at the positive plate from the very commencement of charge when the density of the acid was 1·034 and over. No very exact determination of the oxygen wasted in oxidising the acid could be made, but it was very appreciable in amount, and traces of persulphuric acid were found in the drippings from plates which had been standing idle some days. The surface of the plates was found to consist at the end of charge of peroxide of lead impregnated with persulphuric acid for the positives, and metallic lead containing traces of hydrogen at the negatives. The acid from the negatives contained traces of persulphuric acid.

Physical and Chemical Constitution after Discharge.

Analyses of the positive plates after discharge showed that they consisted of a mixture of peroxide of lead, oxide of lead, and lead sulphate, and that while there was always a relation between the total quantity of peroxide reduced and the ampere hours, there was none between the sulphate of lead formed and the latter.

As to the electrolyte, its density became lower during discharge and persulphuric acid decreased.

The negative plates were found to consist after discharge of lead and lead sulphate, and the lead sulphate formed showed a close agreement with the amount required by theory.

Discussion of the Results.

The high initial E.M.F. is ascribed by the author to the joint action of the small quantity of occluded hydrogen in the lead plates, and the persulphuric acid at the positive plates, while the energy furnished during the steady part of the discharge is attributed to the reduction of the peroxide of lead to some lower oxide and the oxidation of the lead plate. In both cases sulphating follows from local action. In support of his view that the primary action of discharge is the formation of some oxide, the author describes the result of discharging a cell containing a solution of sodium sulphate as electrolyte. The E.M.F. was slightly lower than with sulphuric acid, and no lead sulphate was formed, but the surface of the plate after discharge consisted of a mixture of metallic lead and the sub-oxide of lead.

On charging the cell persulphuric acid is formed at the positive plate, and peroxide of lead is formed by degrees as the charge proceeds, some lower oxide being the first product, as shown in the following equations :—

$$(1)\ Pb + 2SO_3 + O = PbO + 2SO_3.$$

$$(2)\ PbO + 2SO_3 + O = PbO_2 + 2SO_3.$$

The action of persulphuric acid during charge is to bring the whole of the active material to the peroxide state, and the author points out that unless the conditions are such that the existence of this body is possible, peroxide of lead is not formed by electrolysis.

Application of Lord Kelvin's Law.

At the commencement of discharge the law is in practical harmony with observed values, whether water or sulphuric acid is regarded as the electrolyte, if the presence of persulphuric acid is allowed for, the E.M.F. in the two cases being 2·07 volts and 2·15 volts respectively ; but during the steady portion of the discharge which is due to the reduction of PbO_2 to PbO the application of the law only gives an E.M.F. of 1·32 volts, while the observed E.M.F. for lead and PbO_2 in sulphuric acid is 1·6 volts, that is for a PbO_2 plate which has been washed and dried to free it from peroxides. On replacing the clean lead plate by one of spongy lead, without touching the positive, the E.M.F. rises to 1·93 volts. The author concludes therefore that the apparent want of agreement between Lord Kelvin's law and the results of experiment is due to the physical state of the lead plates, and points out that both Schützenberger and Gore have shown that certain metals, amongst which is lead, are not obtained in their normal state by electrolysis, and that they give out heat on passing into it.

SPECIAL NOTICE.

With the present number of "THE ELECTRICIAN" is issued a fine STEEL-PLATE PORTRAIT of LORD RAYLEIGH, M.A., D.C.L., LL.D., F.R.A.S., F.R.G.S., &c., with Autograph.

Subscribers to "The Electrician" should receive this Supplement Gratis, and complaints of non-receipt should be promptly addressed to the Publisher of "The Electrician."

INDUSTRIAL ELECTROLYSIS.

A tyro in technology confronted with the problem of preparing any one of the less complex products of modern industrial chemistry, and acquainted with the elementary truths of electrolysis, would certainly not hesitate to recommend the adoption of a method which went straight to the object aimed at, formed few or no bye-products, and consumed energy only in quantity directly proportional to the useful work effected. It may well be that these surface recommendations are largely the cause of the prevalence of the tyro in the domain of the electro-chemist. Far be it from us to sneer at effort more or less amateur; those who are in a position to transform the crudities of guerilla attempts into fully-elaborated evolutions of the industrial army have to a certain extent neglected their trust and ignored the possibilities of the new weapon presented to them; and any endeavour on their part to decry the enterprising, if somewhat irresponsible, tactics of their irregular comrades would come with singularly bad grace. There is no denying, however, that the best of amateur technologists make rather a ragged squad, even when individually efficient; what then must be the condition of a regiment of which the members themselves are indifferently equipped? Dropping our military simile, let us ask what prospect of success is possessed by the *soi-disant* electro-chemist who is not only unfamiliar

Digitized by Google

with the exigencies of modern chemical manufacturing processes, but is imperfectly acquainted with the principles on which they depend? But one answer is possible.

The mingled ignorance and indifference that have delayed the development of industrial electrolysis by something like a score of years, owe their persistence mainly to the fact that, for their dissipation, men of special training and powers were required, who should be at once sound chemists and competent electricians; and, as in all similar cases where a subject lies on the border line of two others, older and already received as the basis of reputable professions, persons uniting these qualifications were rare, and chary of rubbing shoulders with the somewhat shady adventurers who make borderlands of all kinds their hunting-ground. It is, therefore, with peculiar satisfaction that we find one at least who has abandoned this attitude of aloofness, and done something to map out territory already discovered, and to indicate its capabilities. Mr. JAMES SWINBURNE has collected into a lengthy but lucid Paper the chief facts essential to an understanding of the present position of electrolytic processes of all kinds, and has thus brought into a compendious and accessible form information that was scattered or buried. The Paper which is presented to the Institution of Electrical Engineers is already circulated in proof form; but its discussion will not be taken until after the beginning of the next session, thus inaugurating a healthy reform which we have long advocated. Papers of solid and serious import cannot adequately be considered in the space of one evening, or even two, following immediately on their lection, and there appears no good reason why time should not be accorded for the weighing of arguments and the consultation of references necessary for their intelligent appreciation. If the practice of issuing advance proofs were more general, there would, it is to be hoped, be less of the irrelevant and platitudinary oratory that often converts what should be both pleasant and profitable into a dreary waste of time, temper, and energy. With the individual portions of Mr. SWINBURNE'S Paper we do not propose to deal, lest we anticipate what those who will ultimately discuss it may be intent on saying; but the opportunity of calling attention to the rate, direction and limitations of the development of commercial electrolysis, is too good to be let slip together, and it is with these aspects of the question that we are more particularly concerned.

Taking these in their order, it appears that with regard to the rate of development there is just now a greater activity than there has been for sometime past. This activity must not be measured by the number of new processes that have made their way into the records of the Patent Office, the columns of the technical press, or even into the enterprising hands of the company promoter, but rather by the degree of intelligent investigation that has been allotted to known methods to determine the condition of their successful working and their economic value, and to the demarcation of the limits within which fresh attempts may best be made. Prospecting is eminently useful, and, indeed, indispensable, always provided that the prospector be skilled in his craft. Judged by this standard the rate has been one that should gratify all but those constitutionally impatient. We have seen, for example, the production of aluminium, both by means purely electrolytic, and by other methods employing electrical energy in ways more disputably so, advance from the position of a hopeful suggestion to that of a fact sufficiently definitely accomplished to serve as the basis of a flourishing industry. Even more striking has been the growth of the application of electrolysis to the refining of copper, which has increased, as we recorded the other day, in the United States until the quantity thus treated is quite comparable with that treated by older processes. Less has been done in this country largely because the capital and enterprise that should have gone to its development have been lavished on a particular application of electrolytically-refined copper, which has many other difficulties to contend with than those which beset the path of the refiner pure and simple. What is needed to give the whole industry an impetus that may at once suffice to make it the only process of refining worthy of serious consideration, is the attainment of means whereby the current density, and therefore the rate of deposition, may be raised until the solution and reprecipitation of half an inch or an inch thickness of the metal, may be the work of hours or days, instead of weeks or months. Experiments in this direction have already been made by Mr. SWAN, and their realisation in practice will be of importance to the electrolytic copper refining industry almost equal to that which made it possible—the introduction of the dynamo. That the difficulty will be ultimately overcome there is no reasonable doubt; no physical reason exists limiting the successful deposition of copper to the slow formation that has been put up with hitherto, and where no physical disability exists, attainment is only a question of time. Less cheering is the account that must be rendered of such advance as has been made in the manufacture of "heavy chemicals" by electrolytic means. The prize is large enough, one would think, to stimulate inventive capacity to its utmost; but beyond a few abortive attempts to electrolyse brine or fused sodium chloride, and to displace bleaching powder with the solution obtained by submitting a solution of calcium or magnesium chloride to electrolysis, little has been done. The ill-success of the former is probably rightly attributed to the anode trouble, and that of the latter to the extremely injudicious assertions with which performances by no means remarkable have been eked out. When it is gravely reported concerning a notorious process that a compound is produced by the electrolysis of magnesium chloride which, though incapable of isolation, recognition, or reproduction by chemical means, is yet endowed with properties that remove it from the vulgar herd of bleaching agents, a doubt arises as to whether the assertion is disingenuous or merely puerile; whichever decision is arrived at, a certain want of confidence is engendered that cannot but be fatal to the industrial development of the process thus introduced and recommended. Viewing the subject, however, in its broadest light, there is no doubt but that progress, though not sensational, has been solid and considerable; nor are signs wanting that its rate is even now increasing.

With regard to the second point which we have elected to investigate, it is less easy to speak positively. The direction in which the application of electricity to chemical and metallurgical processes is tending is less definite than the fact of the progress itself. Perhaps the path at present most persistently pursued is rather that leading towards the perfection of methods of electric heating than of processes depending strictly on electro-decomposition. The electric furnace is a mighty instrument, allowing, as it does, the concentration of almost unlimited energy within narrow limits, and the results of its adoption are what might have been expected from a consideration of that property. Its potentialities were recognised by us in an article published some time ago, when nothing more than its application for a few limited purposes had been generally realised; and already it has taken its place, not only in commerce, but as a useful laboratory tool, which will soon be as indispensable as an oxygen-injector furnace. The reasons for its utility are not far to seek; when

Digitized by Google

to the capability of producing an all but limitless temperature is added the absence of waste from the conduction of heat at high temperatures through refractory walls, and the complete absence of products of combustion with the inevitable removal by them of a portion of the very heat they have been called into existence to obtain, no wonder need be felt that attempts to take advantage of these desirable qualities are legion. Beyond the more immediate future, however, it does not appear likely that this preponderance of electric heating over truly electrolytic methods will persist. The true province of the application of electrical energy to chemistry and metallurgy is to be found where scope is given for its dirigible qualities and selective action, and these are not to be attained by any electric furnace.

Finally, with regard to the limits within which advance is practicable in the present state of our knowledge. They are set by the high cost of electrical energy as compared with that of its older rival, heat. Such other difficulties as undoubtedly exist are only hindrances and not true limits, for their removal involves no reconstruction of the order of things as we at present know them. Take for example two that we have already touched upon in another aspect. It would involve no alteration of any idea of importance if an anode were devised capable of serving in the electrolysis of sodium chloride without serious disintegration, but it might revolutionise the alkali trade. Again, there would be nothing very startling in the ascertainment of conditions under which a current density of 100 amperes per square foot could be utilised in the electrolytic refining of copper; yet it would, we submit, be of some slight importance to the refiner. But a successful plan for obtaining 90 per cent. of the energy locked up in coal, in the form of an electric current, would be an alteration of a much more revolutionary character. Then it would be almost optional whether the heat that can be got by burning coal were used directly, or converted into electrical energy, conveyed to a distance and again turned into heat on the precise spot where it was needed. There would be no question then as to whether it would be worth while to use the electric furnace, for the only possible objection to it would have disappeared, nor would manufacturing chemists hesitate to embark in the resolution of an electrolyte merely because the amount of energy required was considerable. Of such nature is the limit, and pending the attainment of the millennium that it defines we must be content to improve existing methods to the utmost extent of their capabilities, in order that their development may, upon its arrival, proceed apace.

REVIEWS.

The Alternate-Current Transformer in Theory and Practice. Vol. II.: The Utilisation of Induced Currents. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. (London: *The Electrician* Printing and Publishing Company, Salisbury-court, Fleet-street.)

In reviewing the first volume of this work nearly two years ago,* we found much to admire and praise, much that raised high expectations for the volume which was to follow. These expectations have by no means been disappointed in the volume before us, which deals with the utilisation of induced currents. The new volume is in many ways of even greater interest than its predecessor. It begins with an account of the historical development of the induction coil, tracing it back through the researches of Ritchie, Hearder, Poggendorff, Foucault, Page, Callan, and Sturgeon, to those of Joseph Henry. His flat spirals, it would seem, rather than the earlier ring of Faraday, must be taken to be the direct ancestors of the modern induction coil. The name of Bachhoffner, who was the first to recognise the value of a divided iron core, is almost unknown in electrical work. Nevertheless, the author shows with what good right this may be claimed for Bachhoffner. He also remarked that it was Sturgeon who gave to the induction coil the general form which it has retained ever since for medical and spark purposes. Modern transformers for electric lighting date from 1878, in which year numerous British patents were applied for. In dealing with the work of successive inventors a well-deserved word of praise is given to Gaulard and Gibbs for the boldness and constancy with which they insisted on the value of the transformer methods of distribution in the face of doubt and even of ridicule. They may not have been the first; but they did a very great service to the industry by their unwearying efforts. This historical review goes on in Chapter I. for about a hundred pages, when it abruptly changes into an elementary theory of modern transformers. Chapter II. opens with distribution by transformer systems as carried out by various firms whose machinery and modes of operation are described. Amongst others the automatic regulating devices of Ganz are very fully dealt with, and several central stations erected by this firm are described in great detail. Here we come upon some inequalities in the work; for whilst the systems of Ganz, Westinghouse, and of the Metropolitan and Thomson-Houston Companies are very fully described, those of some equally deserving rivals are less fully given. The high-tension (*sic*) fuse of Ferranti is given, but not the high-tension fuse of Mordey, which has certainly some advantages. Chapter III. is devoted to central stations using alternate currents. This is an excellent chapter; but it might, if taken alone, lead the reader to suppose that central stations using continuous currents were relatively very unimportant trifles. Professor Fleming thinks (p. 337) that continuous currents cannot be used for systems of supply beyond a mean distance of one mile. In the midst of the Central Station chapter we are suddenly plunged on pages 354 and 355, into a mathematical discussion of the problem of coupling alternators in parallel. In respect of this vexed question the author appears to have adopted the views of Mr. Mordey rather than those of Dr. Hopkinson, Mr. Kapp, or Mr. Swinburne. Chapter IV., on the Construction and Action of Transformers, is by far the most valuable portion of the work, and gives useful summaries of the results obtained in the researches of Ryan, Ayrton, and others, including the recently developed methods of measuring power in alternate-current circuits. In searching it through, however, it does not appear that the author gives in any place directions by which the plain man can design a transformer that shall have any given output and percentage of "drop" and of efficiency. Chapter V. deals with electric welding and other practical uses. There are a large number of interesting and important matters with which it is impossible to deal adequately in any review. The change-over system used at Rome; the white glazed bricks employed in central stations in London; the "booster" used to compensate drop on long lines; the plan of firing devised to economise fuel on a bad diurnal load-curve; the unexpected "Ferranti-effect"; all these and many more points catch the eye as one turns over the pages.

NOTES ON SUBMARINE CABLE WORK.*

BY H. D. WILKINSON.

(*Continued from page 277.*)

15. Slipping Splice.—At the spot where the splice is slipped overboard various data are ascertained with the view of correctly indicating its position on the chart, and assisting in any future repair work in that locality. As far as nautical matters are concerned, the officer on watch takes the latitude and longitude of the position, and if the repair is being effected within sight of the coast the angle between two points on the shore,

* All rights reserved.

Digitized by Google

as viewed from the ship, is accurately measured. For instance, in the repair of a break about six miles from Bonny (West Africa) in the coast cable between Brass and Bonny by the cable ship "Great Northern" (Eastern and South African Telegraph Company), the land bore 96 degrees between Calabar Point and Peter Fortis Point at the spot where the first splice was made after removal of the break. But the electrician requires to know more than the exact geographical position of the splice. He knows the type, the weight, the insulation, and conductor resistance of the few miles of cable he is about to lay in the sea, and he is also aware of any special peculiarities that may exist in it; but, in addition, he wants to know something about the conditions the cable will be subject to when it leaves the ship, and rests on the sea bed. In short, he ascertains the bottom temperature, the depth, and the character of bottom at this particular spot. The cable is almost a personality in the electrician's point of view. He is acquainted with every mile of cable laid in during repairs, and the conditions peculiar to each individual repair fasten themselves upon his mind in such a manner that, on the appearance of a fresh fault in any cable, with his knowledge of the nature of bottom, the depth, temperature, amount of slack and cross currents, he can, when he knows the locality, descend in imagination to the very spot, and say what has most probably caused it.

The subject of deep-sea sounding in connection with apparatus used in the recovery of samples of bottom is one of great interest and importance, more especially so in the investigations carried out in the selection of a route for a new cable. The details of this very interesting subject will be discussed in a subsequent chapter on the laying of cables, so that it may suffice at present to say that most repairing steamers are now fitted with some modification of the sounding apparatus first successfully introduced by Sir William Thomson, now Lord Kelvin. The chief features of this apparatus are the use of pianoforte steel wire, of about 0·03in. diameter for sounding, an arrangement to brake the drum in proportion as the weight of wire payed out increases, and a small steam engine for heaving in the wire after a sounding. By means of the brake action, which, in the modern improved machines is automatic, the weight of the sinker and wire payed out is nearly compensated for, so that the drum in paying out revolves only by a slight excess of the weight of wire over the back pull of the brake. On the sinker touching bottom, the drum is immediately brought to a standstill by the brake, when the measurement of the depth can be read off by the number of revolutions made. Without the gradually increasing brake action the difficulty was to know when the sinker had reached bottom, as the drum continued to revolve after this had occurred, owing partly to the weight of the wire and the momentum acquired. But this difficulty vanished with a closer observation of the behaviour of the wire in descending. On this point Mr. Edward Stallibrass, in his exhaustive Paper on "Deep Sea Sounding in Connection with Submarine Telegraphy," read before the Institution of Electrical Engineers, in November, 1887, says, "If a fair rate of paying out is maintained, by means of a sufficiently heavy sinker, and if necessary by diminishing the brake power, there is no difficulty in detecting when bottom is struck. This is observed by the sudden diminishing of the speed at which the wire runs out. With practice it is easy to distinguish between this and any slacking due to movement of the ship." The sinker, which commences to descend at a speed of about 300 yards per minute, gradually slackens down to half this speed at 2,000 fathoms. For depths exceeding this the weight of the sinker is usually about 60lb. Various devices for automatically detaching the sinker on touching bottom have been patented, to which we shall refer later. The manufacture of the steel wire has recently been improved, lengths being now obtainable up to 7,000 fathoms, so rendering unnecessary any joins in the wire.

A simple automatic attachment to a sinker for bringing up specimens of bottom is shown in Fig. 49. The cup-shaped jaws are kept apart during descent by two little levers mounted on spindles, whose bearings are in the side of the gun-metal cups. The brass stem supporting the jaws screws into a bush in the interior of the lead sinker, as shown, and a stout spiral spring bears down on the top of the jaws, to close them instantly the levers fall. This occurs on touching bottom, when the impact tends to open the jaws a little wider, and the levers instantly fall; the jaws then snap together, trapping between them a sample of the bottom. In this particular design, introduced by Messrs. Johnson and Phillips, the sinker is heaved up with the sounding wire.

In the measurement of temperatures at the bottom of the sea, specially designed thermometers are employed to resist the great pressures met with. In Sir William Siemens' electrical thermometer the resistance of a coil of insulated wire immersed in a bath on board is, by adjusting the temperature of the bath, made equal to that of a similar coil sunk in the sea. When the bridge balance shows the resistances of the coils equal the temperature of the bath is that of the sea below. In the Miller-Casella registering thermometer, a modification of Six's thermometer, the effect of the sea pressure is prevented from acting directly upon the mercurial column by enclosing the latter in a second tube of glass. This jacket is three parts filled with spirit, and the air exhausted from the remaining part, so that contraction of volume can take place in it without affecting the mercurial column. This form of thermometer has been most successful in various expeditions, and with some modifications, to which reference will be made in a further portion of this series, is now universally used. The temperature at the bottom of the sea is what is required to be known, and the thermometer must therefore register the bottom temperature without being affected by passing through warmer or colder strata of water on its way down or up. Mr. J. Y. Buchanan, F.R.S., a member of the scientific staff of the "Challenger" expedition, and since connected with some cable route surveys, has devised the "Mercury Piezometer" which registers the temperature at the greatest depth to which it is

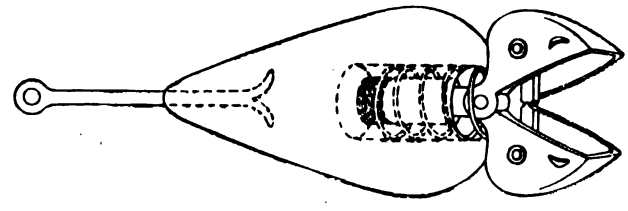

Fig. 49.—Sinker, for bringing up specimens of sea bottom.

lowered. The capsizing thermometer of Negretti and Zambra also effects this very well in moderate depths. Temperatures at the bottom of all the great oceans closely approach freezing point, the Atlantic at 2,000 fathoms depth being 36° F., the Pacific being a degree or two lower. The Mediterranean Sea is in this respect an exception on account of its comparatively shallow connection with the Atlantic through the Straits of Gibraltar. The temperature even at the greatest depths in this sea is never below 55° Fahr.

The condition of low temperature is most favourable for submarine cables. The conductivity of the copper conductor and the resistance of the insulator are both thereby increased. The great pressure of sea water on the ocean bed also increases the insulation resistance, most remarkably so in the case of gutta-percha. On this head, information obtained at the time of laying a cable is most valuable in subsequent repair work in the same waters. After submersion the contractors carry out daily tests of the cable for one month, and amongst other determinations they measure very carefully the resistance of the conductor making all corrections for temperature of testing room. On comparing this with the resistance of the cable as measured at the standard temperature of 75° Fahr. in tank at the factory, the mean temperature of the sea in which the cable is laid is arrived at.

The nautical position of the splice is subsequently marked on the cable chart with the date attached; but the electrician also requires to know the distance of the position from the shore, as measured along the cable, which is a different thing. This he finds by a resistance test of the conductor before the new end is spliced on, the man on shore earthing cable during test. After the result is corrected for temperature of sea and perhaps checked by a return test from shore while ship earths, the distance of the position in knots

Digitized by Google

from shore is obtained by dividing the result in ohms by the number of ohms to the knot at standard temperature, which is known.

The arrangements for slipping the finished splice overboard depend upon whether paying-out is to be done over the stern or the bows. Diagrams representing the deck of the vessel in plan, showing the position of the cable and gear in each case, are given in Figs. 50 and 51. When it is intended to pay out over stern, as in Fig. 50, the end of cable in tank before splicing is led aft through a set of brake clamps, over drum, under dynamometer pulley and over stern sheave, whence it is passed, as shown in the illustration, outside ship and brought up on board again over one of bow sheaves. When a sufficient length for splicing is hauled on board the cable is stoppered at bows, and the splice completed in the manner described. The end of the other part of the cable is similarly stoppered, and these fixed stoppers at the bow baulks are used to slip or ease away the cable through until the length of bight inboard is as small as possible. Another stopper is then attached at each side of the bight just outside the sheaves, each stopper having a round thimble in it. A drum rope, say 3½in., is then led from picking-up drum and threaded through the thimble, and the end made fast to bullards near fish davits.

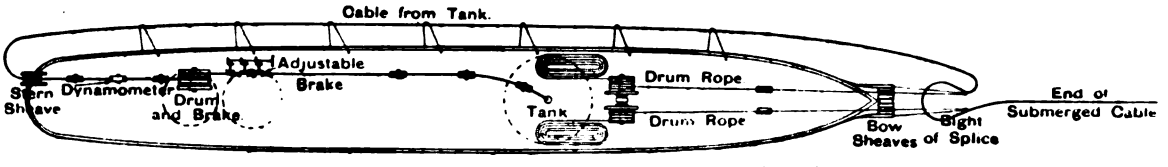

FIG. 50.—Slipping Splice. (To pay out from Stern.)

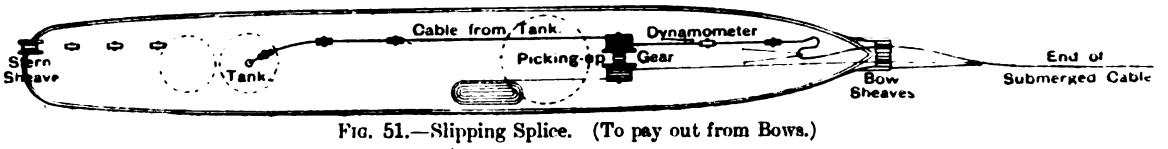

FIG. 51.—Slipping Splice. (To pay out from Bows.)

This being done on each side of bight, as shown in sketch, the drum ropes are heaved tight to take the strain while the fixed stoppers are removed. A heaving line is then passed through the bight to guide it while riding over sheaves, and the cable is then lowered by slacking away on both drum ropes. When the bight has passed clear of the sheaves, the heaving line is run clear of cable, and when sufficient length of drum rope is payed out the ends attached to bullards are let go, and the ropes run clear through the thimbles of the stoppers

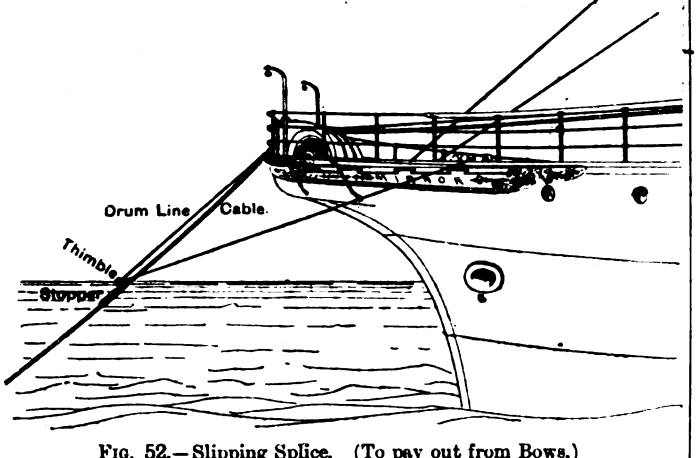

FIG. 52.—Slipping Splice. (To pay out from Bows.)

fastened to cable. Along the ship's side, at convenient distances, are placed men with hand slip ropes, the bights of which suspend the cable, as shown in the figure, and as the strain comes on them they are let go in rotation. By this means the strain due to weight of cable as it sinks is checked, and does not come suddenly upon ship's stern. Should the wind and current come from the right direction during this operation nothing more than the above procedure is necessary, but if otherwise a stopper and thimble is previously put on cable immediately over ship's quarter, with a drum rope rove through thimble, and fixed in such a manner as to be able to take the full strain on the cable before it reaches the propeller. The rope is then slacked away gradually while ship is manœuvred into a position in which the strain takes cable clear of the propeller. This done the cable is in position over stern sheaves ready for paying out.

The set of brake clamps for paying out alluded to above and indicated in the sketch, are semi-circular blocks placed alternately on a table, between the surfaces of which the cable passes. The blocks on one side are fixed and on the other side movable together by a shaft with bevel pinions turned by a hand wheel. As the brake is applied the movable blocks move towards the fixed ones, forcing the cable between them to take a slightly zigzag or wavy course, which rapidly imposes a resistance to its speed of movement. This is found a most necessary adjunct to the ordinary brake on the paying-out drum, when long lengths of cable have to be payed out from tank, as in laying new cables, but is not necessary in the paying out of short lengths in repair work.

When paying out is to be done over ship's bows the end of cable in tank is taken forward over picking-up drum and under dynamometer pulley previous to splicing, the seaward end being heaved in to allow a sufficient length for making splice and then stoppered inboard at bow baulks (Fig. 51). When the splice is complete, a stopper is put on outside ship, and cable lowered away, as described above, until the strain comes upon the cable inboard, when the rope is slipped, and everything is ready to pay out. This operation is shown in Fig. 52, the bows of the steamer shown being that of the cable ship "Mirror" (Eastern Telegraph Company). The bow baulks in this steamer are fixed in a position agreeing with the outline of the cutwater, giving a snug and yacht-like appearance to the bows. The bow gear is the design of Mr. W. J. Johnson.

(To be continued.)

THE BATTLE OF THE "PHASES."

It has not been until recently disputed that the three-phase motor has an advantage over the ordinary Tesla (two-phase) motor, in so far that it possesses a more constant and uniformly rotating magnetic field. Mr. J. F. Kelly, in the *Electrical World* for April 16th, calls this advantage into question, and in a mathematical article attempts to show that the reasons advanced by Herr Dolivo-Dobrowolsky for the superiority are not simply insufficient, but non-existent; and that, consequently, if such superiority really exists, some other explanation must be found for it. In replying to this attack, Herr Dobrowolsky, in the *Electrical World* for July 2nd, in the first place states that such authorities as Mr. Gisbert Kapp and Prof. Ferraris have acknowledged the correctness of the conclusion that the greater the number of phases employed the more constant in strength the rotating magnetic field becomes. He then proceeds as follows:—

"I do not care to go into mathematics, but will limit myself to ordinary logic. If the motor had an absolutely constant and uniformly rotating field, it should develop during every moment absolutely the same mechanical energy, and should,

Digitized by Google

therefore, also consume during every moment absolutely the same amount of electrical energy. The electrical energy which is delivered to the motor is in watts. With a *sinusoidal current* the watts also follow a sine law. On the other hand, if we have two alternating currents which differ in time by one quarter of a phase the waves of the watts which the motor receives differ also by one-quarter of a period. The energy which the motor receives is the sum of the watts of the two currents. But the sum of the two sine curves of the watts is not constant, and varies by about 40 per cent. It follows from this that the motor receives energy from the line which is not constant from one moment to the next, but which pulsates. As long as the mechanical inertia of the motor is not considered in the theory of the motor, it may be assumed that the work delivered by the motor is likewise not constant from one moment to the next. Whether this is to be explained by saying that the field intensity alone pulsates, or that the speed of rotation of the field oscillates, is quite immaterial. In any case we see that the speed and torque of a two-phase motor cannot be as uniform as it would be if the field was rotated mechanically and had a permanent magnetism. The more phases we use the nearer will the watt curves come together, and the more uniform will be the electrical energy which is applied to the motor and the mechanical energy that is given out by the motor."

Referring to non-sinusoidal currents, Herr Dobrowolsky states that it is useless, with the view of obtaining greater uniformity in torque, to design the machines for currents of some special shape, for a particular form of current curve can be developed for one output only. "There has, doubtless, been sufficient proof published in the electrical literature that the sine form is the only one which is stable and easily produced. If by reason of some improper proportioning of the dynamo it produces any other currents (for instance, pointed waves), it will always be possible in a motor to have a uniform rotation of a constant field, if one will only use very many phases. As three-phase currents require no more leads than when two-phase are employed, the use of three phases is not accompanied by any disadvantage, and I am sure that the two-phase current now belongs to the past. If one wishes to obtain more phases with three leads, one can use the method that I suggested a year ago, and called 'double-linking,' which has been described in a number of Papers, and is patented by me. There has also been much said against the properties of the three-phase current motor. It is claimed that the motor cannot be started loaded. How do these critics know this? I have always claimed in my writings and Papers that the motors which I have built developed a large torque at starting, which statement is based on *experience*. If there still exists a doubt, there remains only for me to request the unbelievers to examine my motors. Then I will take pleasure to connect large as well as small motors with a brake, and start them with the brake applied; this I did repeatedly before I made the published statement. Mr. Stanley and many others claim that 10 and even 20 H.P. transformers will be necessary for a 2 H.P. rotary field motor, because such a large exciting current is required. I published in the *Elektrotechnische Zeitschrift* complete data of tests made with a 2 H.P. motor in April, 1891. Those who will study this article will find that the motor when running unloaded has a phase difference of about 72 degrees between the current and the voltage, but when delivering 2 H.P. this was only 28 degrees, and with 3 H.P. 22 degrees. With normal load, namely, 2 H.P., it consumed 1,830 true watts, as compared with 2,079 apparent watts. It is plainly stated that with a load of 2 H.P. there were 9·9 amperes in each of the three currents at 70 volts. Therefore one does not require a 20 H.P. transformer for running such a motor, but only one which is built for three times 9·9 amperes at 70 volts, namely, for 2,079 watts; this would equal only about 2·8 H.P. In the same article I call especial attention to this very small phase difference, and state the ratio

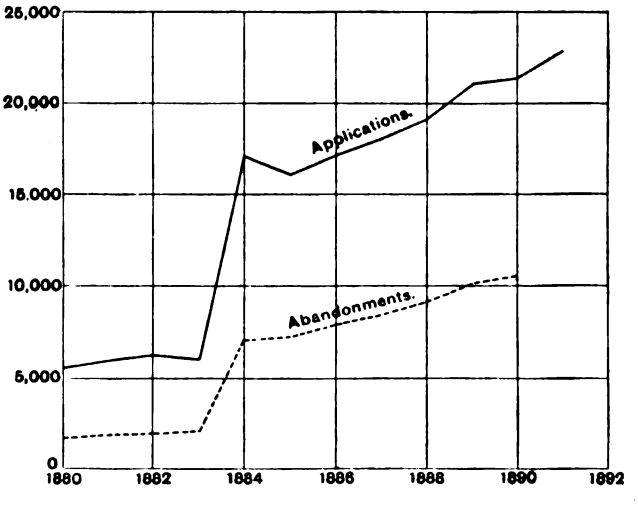
$$\frac{\text{1,830 true watts}}{\text{2,079 apparent watts}} = \cdot 88 = \text{cosine of angle of lag,}$$

is a very favourable one for such a small motor, aside from the total efficiency of about 80 to 81 per cent. at full load, and 75 per cent. at half load, and the possibility of delivering 4 H.P. for a short time without great sacrifice in economy."

Mr. Kelly replies, in the *Electrical World* for July 16th, that the figures given by Herr Dobrowolsky, while they show a high degree of merit in the three-phase motor, are not sufficient to prove it better than the two-phase motors built by the Westinghouse Company. A proof is given that the power supplied by two quarter-phase currents, such as those used to drive a Tesla motor, is the same at every instant. The correctness of the proof, however, depends upon the assumptions that the currents follow the sine law, and that the two circuits are symmetrical, so that the same phase difference between the volts and amperes obtains for each circuit. Accompanying Mr. Kelly's article is one by Mr. C. P. Steinmetz, who shows that it is a fundamental law that in any symmetrical system of polyphase currents, whether two, three, or any number of phases are used, the sum of the instantaneous values of the watts supplied by the different circuits is constant. He states that it is for this reason that a polyphase system can be so easily transformed from one number of phases to any other. These advantages are, however, as fully present in the case of quarter-phase currents as for the three-phase ones; and Mr. Steinmetz considers that the only advantage of using the latter lies in the fact that the greater the number of phases the less will be the objectionable effects consequent on deviations of the current from the true sine law. The success of the three-phase system in Germany is attributed to the low frequency of the currents employed, and the prominent attention it has received to the accidental connection with the Frankfort-Lauffen high-pressure experiments.

THE INCREASE IN PATENT OFFICE BUSINESS.

In the report of the Comptroller-General of the Patent Office on the proceedings which took place in his Department during 1891, the general business compared with that of previous years as far as 1884 is given in the form of tables. These tables show a steady increase in the number of applications, but these are accompanied by a formidable number of abandonments.



We have consulted the statistics of former years, and have prepared a diagram showing the remarkable effect of the Patent Act of 1883. Prior to 1880 there was a slow rise in the number of applications, while the abandonments were nearly constant at about 2,000 per annum. In the year preceding the new Act there was a decided falling off in applications, due, of course, to patentees who were in no particular hurry, and who preferred to wait for the lower fees; but it is to be observed that the abandonments were hardly affected. Then comes a rush both of those who had been holding back and of the thousands who were encouraged to try their luck; and this was followed by a falling off of about 2,000, after which the applications have increased rapidly, and show as yet no signs of exhaustion. The abandonments, however, have risen from about one-third to one-half. It must be remembered that there is, as it were, a lag between the two curves, the majority of the

Digitized by Google

abandonments dating nine months after the corresponding individual applications.

We take this opportunity of reminding our readers that the reduction in patent renewal fees proposed by Mr. Goschen in his recent Budget will, by order of the Board of Trade, come into operation after September 30th prox. The following is the new scale compared with the old:—

Fifth year's	tax	£5	instead of	£10.
Sixth	„	£6	„	£10.
Seventh	„	£7	„	£10.
Eighth	„	£8	„	£10.
Ninth	„	£9	„	£15.
Tenth	„	£10	„	£15.
Eleventh	„	£11	„	£20.
Twelfth	„	£12	„	£20.
Thirteenth	„	£13	„	£20.
Fourteenth	„	£14	„	£20.

The fees payable on enlargement of time for paying the above taxes will also be reduced as follows:—

Not exceeding	1 month,	£1	instead of	£3.
„	2 months	£3	„	£7.
„	3 „	£5	„	£10.

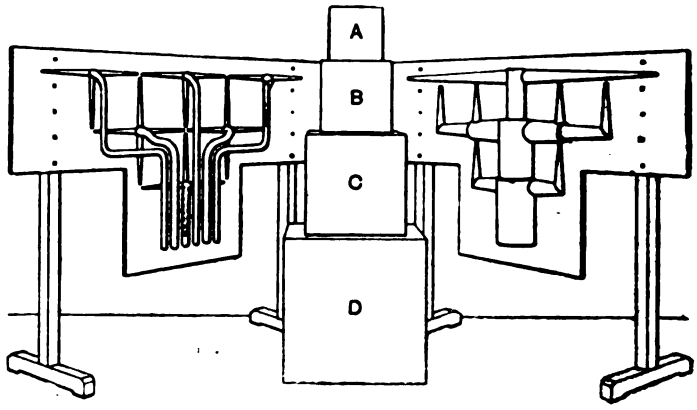
The above reduced scale will be applicable to all patents in force. The result is a total reduction of Government fees on a 14 years' patent from £154 to £99, *i.e.*, £55.

ELECTRICAL MODELS FOR LAW COURTS.

We referred some little time ago to the elaborate models which had been specially constructed for the purpose of assisting counsel's explanation of the principal points in the Edison feeder-patent case, which had then recently occupied the attention of the American Law Courts. Mr. W. J. Jenks, of the Edison Electric Light Company of New York, has been good enough to send us some excellent photographs of these models.

The apparatus consisted of an ingenious and instructive arrangement of glass and metal pipes, rotary pumps, and turbines, running on horizontal axes, representing respectively mains, dynamos, and motors or lamps. The pipes contained fluid, in which coloured globules could no doubt be arranged so as to render its circulation plainly visible. Glass gauges, representing voltmeters, indicated the hydrostatic pressure at different parts of the circuit by the height at which the water stood in them. The fall of pressure over a circuit, as influenced by the amount of current flowing, was thus very clearly exhibited.

These models promise to be particularly valuable in making plain the somewhat complex actions which take place in the three-wire and similar compensating systems. In the middle or "neutral" conductor of a three-wire system, for example, the liquid might be made to flow in one direction in one part of its length, in another direction in another part, and, perhaps, in an intermediate position it would remain at rest. Mr. Jenks tells us that other models are being made, and the idea, although no doubt very valuable for merely illustrating electrical phenomena in law courts, should also be of great educational value in schools and technical colleges, where, of course, the limitations of the hydraulic analogy would be carefully pointed out.



A. This Cube represents $\frac{1}{150}$th of Mass of Copper Conductors required for the nine City Blocks shown in Models containing 8,640 Lamps of 16 c.p. by Three-Wire Feeder System. B. Ditto, by Two-Wire Feeder System. C. Ditto, by Three-Wire Tree System. D. Ditto, by Two-Wire Tree System.

Amongst these "object lessons" intended for the enlightenment of the legal mind were a number of boards on which were mounted models, showing the bulk of copper required in the different systems of distribution. We reproduce a sketch of these particular models.

These designs are due chiefly to Mr. W. J. Jenks, and the details were worked out by Mr. A. E. Kennelly, of the Edison Laboratory, Orange, N.J.

THE JENKIN CLIP FOR CONNECTING HOUSE SERVICE WIRES.

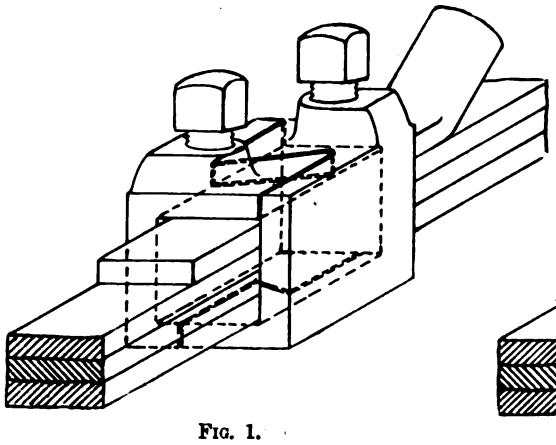


Fig. 1.

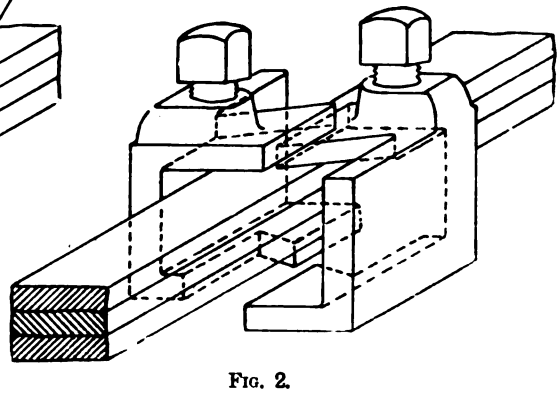

Fig. 2.

A handy form of clip connection for connecting house service wires to copper strip has been designed by Mr. B. M. Jenkin. In Fig. 1 the clip is shown in place clamping down a house service end on to the three flat strips forming the main. The clip is in two pieces, and so shaped that when the fourth strip is in it cannot fall off, even if the screws should be loose, while, when the extra strip is taken out, one half of the clip can be pushed down below the other and pulled off sideways, as shown in Fig. 2. The clip thus makes a purely mechanical connection, one which can be made anywhere along the length of strip, which cannot fall apart, but which can be disconnected with the greatest ease, and without risk of short-circuiting between one line of strip and the next line parallel to it.

THE PROBLEMS OF COMMERCIAL ELECTROLYSIS.*

BY J. SWINBURNE.

It would be idle to attempt to go over the whole subject of the technical applications of electrolysis, as, although this development of industry is of very recent growth, it is already so extensive that many of its branches demand evenings devoted exclusively to their discussion. My object is, however, to take a sort of bird's-eye view of the subject, and, if possible, to try to foresee the directions in which others must seek for future developments.

There is a very general feeling that there is a mine of untold wealth in the application of electricity to metallurgy; but chemists are not generally electricians, and electricians are seldom chemists. It seemed, therefore, advisable to bring the Paper before this Institution, in the hope that it will result in a discussion; and if it leads to the expression of the views, both of electrical engineers and manufacturing chemists, and to a further approach to common ground, our time will be well spent.

However puzzling the theory of electrolysis may be, for commercial purposes it may be regarded as involving no mystery. In fact, broadly speaking, we may disregard the electrical side of the question, and look upon electrolysis as a method of oxidising and reducing, and nothing more. It must be remembered, however, that there are often many ways of oxidising the same substance. For instance, a sulphide may be oxidised into a sulphite or sulphate, or sulphur may be liberated. Electrolysis does not always afford the means of oxidising in the particular manner desired. A very large number of the processes employed in chemical industry consist merely in oxidising and reducing, special conditions being arranged to suit the particular substance being operated upon. Once we take this broad view, all we have to consider is, "Which of the oxidising and reducing processes in use in chemical works can we advantageously replace by electrical methods?" In many cases electrical methods are impossible; in others they are more expensive than those at present in use; but it is hardly too much to say that in an enormous number electrolysis is destined to play a leading part in the near future.

Take, for instance, the case of reduction. This is almost universally effected by means of hot carbon, and at first sight it seems unlikely that it could pay to burn the carbon under a boiler, and get a small percentage of the energy back in the electrical form, and to utilise that portion alone. It must be remembered, however, that the methods of reduction by burning carbon are themselves exceedingly inefficient, and, moreover, they very often give impure products. By means of electrolysis, however, it is frequently possible to secure metals of the highest purity by direct processes. Before going further, it will be wise to form some idea of the cost of electrical energy in, say, a large chemical works. Of course "cost" is a loose term; we might calculate it from the cost of coal and labour and sundries; or we might add interest and depreciation, rent and superintendence. In all cases in estimating the cost, further additions have to be made for standing charges, advertising, profits, maintaining patents, &c. It is unnecessary to trouble ourselves about definitions of cost, for if it is stated how the figures are obtained, the selling price can be worked out and comparisons can be made.

Suppose a plant is put up to give a million watts, it will be found that if the plant is taken as running day and night, including Sundays, and if the best engines, with modern dynamos, are employed, the cost comes out about 0·25d. per kilowatt-hour. This figure includes interest and depreciation of engines, boilers, and buildings, and coal, labour, and petty stores; but does not include rent or salaried superintendence. This figure will appear ridiculous to those accustomed to London central stations; but that is because central stations work under the most disadvantageous conditions possible, while a chemical works has everything in its favour.

Oxidation and Reduction.

Oxygen.—The first obvious application of electrolysis is the decomposition of water. In an acid solution platinum or lead anodes are necessary; platinum is expensive, and lead takes a high electromotive force, so it would be best to use an alkaline solution with iron electrodes. Allowing 2 volts as the pressure required, the cost comes out at 5s. 7d. per 1,000ft. for the oxygen. The hydrogen is taken as valueless. As the output in oxygen must be small, we must take a much higher figure than the farthing per kilowatt-hour—in fact, it would be safer to double the price and say 11s. 2d. To find the selling price we must allow for packing in cylinders, and add all the trade charges, which will probably bring the price up to something like 15s. per 1,000 cubic feet. The retail price of Brinn's oxygen is 2d. per cubic foot, so there would appear to be a very large margin.

Alkali.—We come next to a subject which has already absorbed an enormous amount of labour and thought, and that is the production of caustic soda and chlorine from common salt. The Leblanc and Weldon process is exceedingly complicated and very costly; and as by simply electrolysing salt, costing about 15s. a ton, chlorine and caustic soda can be produced, it seems, at first sight at least, most strange that electrolytic processes have not replaced all others within the last few years. Assuming that the process works, let us first form a rough idea of its probable economy. With suitable vats, and a reasonable current-density, we may take it that 3 volts is a liberal allowance. For the ton of 70 per cent. caustic soda we have—

	£	s.	d.
Electrical energy	2	15	0
Salt	1	2	6
Lime	1	3	0
	£5	0	6

For £5 we have thus obtained a ton of caustic and 1½ ton of bleaching powder. We have allowed nothing for the cost of vats, for labour at the vats and in handling, or for evaporation of causticised liquor. The ordinary caustic liquor after causticising is quite weak, but electrolytic caustic can be made into a strong lye. On a small scale I have produced lye with 30 per cent. caustic. To do this the brine is electrolysed and then stirred up with more salt, and so on; the process being repeated several times. Strong caustic is a good conductor, so this method is good from that point of view as well as from that of saving in evaporation. Evaporation with a Yaryan should not come to more than a shilling or two a ton extra. It would doubtless be safe to say that, taking this way of estimating the cost, a ton of caustic and a ton and a-half of bleach should be made for £6. This allows an enormous margin for expenses and for profits. This method of estimating is very rough; and unless a new process worked out in this sort of way comes out with an enormous margin, it is not likely to be worthy of serious consideration. On looking into it further, it will generally be found that when all the details of expenditure which will be necessary in practice are added, the margin, if it still exists, is too small. In fact, a new process must look marvellously good on paper to be really worth anything when tried commercially. Electrolytic soda and bleach seem to have an excessive margin, however, and we have to see whether there is any other weak point.

I believe the difficulty, and the only difficulty, lies in the anodes. Process after process is brought out, and each claims to have solved the problem of electrolytic soda by the use of some new arrangement of the porous partition, or by some other detail which can hardly make all the difference between success and failure. The various processes make a little excitement for a time, and then disappear, I believe because the anodes are destroyed.

Of course none of the ordinary metals can be used as anodes, as they are attacked at once. Platinum is generally supposed not to be attacked by chlorine; but I find that it is slowly eaten away. I would like to hear this confirmed or denied by others, for it is a very important point. On the one hand I find experimental anodes eaten away; on the other, we hear of platinum anodes being used extensively in the electrolysis of chlorides. Of course, in the manufacture of such a cheap commodity as soda, the capital invested in platinum anodes would be prohibitive; and the least waste of metal would lead to ruinous expenditure. The next material to consider is carbon. In 1882 Bartoli and Papasogli pointed out that carbon was attacked when used in any solution which evolves oxygen. Without knowing of their work, I found the same thing by a series of experiments carried out in 1883. In those days it was tacitly assumed that carbon with peroxide of lead could be used in the ordinary secondary batteries, without any fear of local action. Though carbon does not seem to combine with chlorine during electrolysis, I find that it is always attacked, even in a solution of salt. I have tried every kind of carbon I can think of, and the result has always been that the anode was corroded. I do not mean to say that carbon is eaten away at a rate at all corresponding to that with which the soda is formed; in comparison the corrosion is slow. It must be remembered, however, that a very slow corrosion makes carbon anodes useless when the products are cheap.

Carbon is also troublesome mechanically. It is difficult to make good contacts with it, especially when there is chlorine about. Large carbon plates are also expensive. Mr. Greenwood overcomes this last difficulty by electro-plating one side of a number of comparatively small plates, and then soldering them to a plate of type metal. The type metal is not exposed to the solution anywhere, else it would be attacked by the chlorine. By this means he produces a large carbon anode with a good metallic connection.

Peroxide of lead seems to present a solution of the problem. Unfortunately, however, peroxide of lead is reduced by hydrochloric acid; and it seems to be impossible to electrolyse salt without producing some free acid at the anode. Some specimens of lithanode I tried were attacked; I do not know, though, whether the inexhaustible ingenuity of Mr. Fitzgerald has produced any special make which will stand traces of free acid. I am inclined to think, therefore, that progress is barred in this direction solely by

* This Paper will be discussed at the Institution of Electrical Engineers at one of the first meetings after the recess.

Digitized by Google

the want of a good anode. If this is the case, there is a fortune awaiting the inventor who can find something which will act as an anode in a solution of common salt.

I have tried electrolysing sodium sulphate. There is not the same margin here. You get hydrochloric acid as a by-product, instead of chlorine, so that the Weldon process would still be necessary; and the sulphuric acid would have to be concentrated every cycle, in order to act on the next batch of salt. This process would, in fact, save the black ash part of the soda process; and, like all these methods, would demand carbonic acid to make soda crystals. Of course, this last is not a serious difficulty, especially if quicklime is needed to absorb the chlorine. In this case I tried lead anodes, when, to my surprise, the small traces of chloride left in the sulphate corroded the lead anodes.

Paper-makers use large quantities both of caustic and bleach, and they recover soda and causticise it on their works. It would therefore be an enormous advantage to be able to produce caustic and bleach direct on their own premises. I do not know if the presence of salt would interfere in any way with the action of caustic in the grass or straw boilers, but should think not. By making the caustic on the spot, a saving is effected in the processes otherwise necessary. There would be no need to concentrate the lye, or to fish out the salt that may be present. Caustic drums and carriage would be saved; but, of course, against this there may be carriage of salt. The importance to paper works is so great that it is almost a question whether it would not pay to face the corrosion of the carbons, and to arrange vats so that the anodes can be easily replaced.

In the Hermite process the chlorine is not given off, but a hypochlorite is formed. Of course, in this case caustic soda cannot be made. For paper works especially it is obviously cheaper to supply lime and get bleaching powder and caustic, than to make sodium hypochlorite only. This may, however, depend on the anodes. Platinum anodes are used in this process, and it seems to be the case that platinum is not attacked in an alkaline chloride. If this is so, it is possible to produce hypochlorite of soda, but not caustic and bleaching powder. The Hermite process is apparently commercially successful. Magnesium chloride is generally employed in the Hermite process, but I have been told that salt is now used. It has been said that electrolytic hypochlorites, especially of magnesium, have more bleaching power than the ordinary bleaching powder. Of course, a sodium, or any other hypochlorite, may be formed which has twice as much of its chlorine available, when compared with bleaching powder; but this is merely an apparent gain, as it takes twice as much electricity to produce the hypochlorite. Messrs. Cross and Bevan, however, hold that the bleaching power of these compounds is not as determined by arsenious acid. They maintain that the fibres to be bleached contain some ketones or other, and these ketones absorb some of the available chlorine, especially when provided by bleaching powder; that the hypochlorite of sodium and of calcium waste available chlorine on the useless work of chlorinating these ketones, while magnesium hypochlorate devotes its whole attention to honest bleaching. Of course, if it is slightly easier to oxidise the colouring matters than to attack the ketones, it may be the case that a hypochlorate of a weak base, like magnesium, may be able to bleach, but not to attack ketones. It would then be better than the hypochlorate of calcium, or especially sodium. These matters are better left in the hands of such authorities as Messrs Cross and Bevan. They make out, also, that electrolytically prepared magnesium hypochlorite is best. This seems very strange. Of course it would mean that some other salt is really formed. The properties of a salt cannot depend on the method of its preparation, and there is no magic in electrolysis.

Potassium Chlorate.—The manufacture of potassium chlorate is carried out by electrolysing a hot solution of the chloride. The chlorate is thenformed instead of the hypochlorite. This process is carried out on a large scale at Vallorbes, in France, under the direction of M. Gall-de-Montlaur. It is stated that they make a ton a day, 24 H.P. hours yielding 2·2lb. The power is supplied by a waterfall, so the chlorate should be very cheaply made, if the anodes are absolutely free from corrosion. Platinum anodes are employed.

The Electrolysis of Fused Salt.

Many inventors have been at work on electrolysis of fused salt. At first sight this also seems most simple. Salt is cheap, and is fusible, and therefore all that has to be done is to melt it and electrolyse it, getting sodium at one pole, and chlorine at the other. The sodium could be sold at a very low price for making aluminium, and for amalgamation in gold extraction, and can, of course, be converted into caustic soda or crystals as desired. Consumers of caustic would buy the metallic sodium, and would add water, thus obtaining pure caustic. The margin of profit in this case is apparently enormous.

The difficulties are, however, very serious. In the first place, sodium chloride boils at a very little above its melting point. The result is that the sodium is obtained mixed with large quantities of salt. Melted salt is by no means a convenient substance to handle. It acts on many kinds of clay, so that ordinary fire-clay crucibles cannot be employed. Chlorine at a temperature corresponding to a red heat is also troublesome to deal with. It is said that chlorine will not attack a dry metal, so that iron can be used for the containing vessel. Most patentees describe vessels of iron with porcelain where insulation is necessary.

We now come to the anodes again. As there is no oxygen present, it would seem as if carbon might be used. Patentees always mention carbon anodes. Retort carbon is eaten away, and so are electric light or artificial carbon rods.

It seems strange that carbon should be attacked, and it would be well for these experiments to be repeated, to make sure that there is no error. Of course carbon is the only hope. Whether the chlorine is dry or not, metals are eaten away with great rapidity. The anodes are corroded chiefly at the surface. In addition to these troubles, the theoretical quantity of sodium is not obtained. Some people have supposed that there is a sub-chloride formed, and that sodium is really not a monovalent metal. This is rather an extravagant notion. I do not know why both sodium and chlorine should not be soluble in the fused chloride without forming any definite compound. So many workers have been unsuccessful with fused salt, that it looks as if there were some insuperable obstacle in the way; and it is questionable whether the ground is worth any further labour.

Electrolysis of Fused Soda.

Castner has recently proposed to produce sodium cheaply by the electrolysis of fused caustic. The temperature is to be high enough to fuse the caustic, but not high enough for the sodium to decompose the fused hydrate forming oxide. Whether this process has had any success commercially, I do not know.

Aluminium.

The extraction of aluminium has long been an important problem. The old method was to replace aluminium in its chloride by means of sodium. This involves the manufacture of metallic sodium, and of the anhydrous chloride of aluminium. The anhydrous chloride cannot be obtained by evaporation of its solution, as the solution gives off hydrochloric acid, and leaves alumina; otherwise the anhydrous chloride would be quite cheap. The price of sodium has been reduced recently by the Castner process, but the extraction of aluminium by ordinary means is still so expensive that electrical methods can compete.

It seems to be impossible to deposit aluminium from any of its solutions, so fused salts have to be employed. The electrolytic processes differ in detail only. The electrolyte is cryolite, or a solution of alumina in cryolite. If cryolite is electrolysed, aluminium is deposited, and fluorine is presumably evolved at the anode, which is made of carbon. I have not seen any account of how the fluorine comes off. Yet in some processes it is stated that cryolite is electrolysed by itself. In the Minet process the solution of oxide is employed, and aluminium is deposited, and the anodes are burned away by the oxygen, giving off, according to some accounts, carbon dioxide, but probably the monoxide in fact. The chief difficulties in the electrolysis of cryolite solutions are due to the cryolite itself, as it attacks all the substances commonly employed for making crucibles. It is, therefore, usual to use cast iron to make the containing vessels or vats, and to heat the electrolyte by electrical power from the inside.

Minet uses iron vats, and arranges a shunt current, which makes the vats to some extent cathodes, so that they are not attacked by the electrolyte. Presumably fluorine is soluble in fused cryolite, and attacks iron. By making it a cathode it is always coated with aluminium, so that any fluorine is taken up in dissolving off some of this aluminium. The importance of preventing the corrosion does not lie so much in the slight saving of iron as in the avoidance of any deposit of this metal in the aluminium. The great difficulty is to get the aluminium pure, and any trace of iron reduces its value for most purposes very greatly. Minet reduces the melting point of the electrolyte by the addition of common salt In the Hall process, carried on at Pittsburg, the electrolyte is practically the same. Calcium fluoride is used to mix with the cryolite, or calcium chloride. The Kleiner, and, I believe, the Hall, processes are carried on in England. The processes have so often been fully described elsewhere, that I need not discuss them at any length here. There is still a great demand for cheaper aluminium; and there is much to be done in making it pure. Aluminiuum has a strang affinity for silicon, and small percentages of silicon and iron are generally present, and are very deleterious.

Magnesium.

This metal is closely allied to aluminium, and is similar with regard to its anhydrous chloride. There is not the same demand for it, as either it does not give remarkable alloys like those of aluminium, or they have not been investigated. It is said to be made on the Continent by electrolysing the double chloride of magnesium and sodium or potassium obtained from the mother liquor

Digitized by Google

after evaporating sea water. The double salt can apparently be rendered anhydrous without the formation of much magnesia.

Zinc.

Proposals have been made to deal with zinc ores electrically. The blend is to be roasted into sulphate, and the solution dissolved and electrolysed. A great difficulty arises in the deposition of the metal. It comes down in trees. Kiliani proposed to use high-current densities, holding that zinc then comes down in the reguline state. Watt prefers to use acetate of zinc as the electrolyte; and alkaline solutions, such as zincate of soda, have also been proposed. I am not aware that zinc has been deposited commercially. Similar processes have been proposed for dealing with the silver-zinc alloy produced in the Parkes or Karsten desilverisation process.

Lead.

So far, little has been done in the way of dealing with lead ores electrically. It has been proposed to make anodes of galena, and to work with lead nitrate as electrolyte, but I have not heard that any such process has been carried out successfully. It is hardly likely that it could, as lead forms troublesome trees in acid solutions. Anyone who has worked with solutions of such salts as lead nitrate would be inclined to give up all hope of obtaining anything like a reasonably compact deposit of lead.

The extraction of silver from lead by the Pattinson process is very cumbrous and roundabout, and is, of course, expensive. Keith started a works in America for desilverising electrolytically. He used a solution of sulphate of lead in sodium acetate as electrolyte. Though the Keith process was brought out some ten years ago, it does not seem to have come into general use. The deposit of lead even from such a solution as sodium plumbite is very bulky and spongy, and is difficult to deal with, as it is apt to decompose water and oxidise spontaneously during handling.

Gold and Silver.

Greenwood and others have proposed to make chlorine electrolytically for catching gold by the chlorine process. As this is exactly the same problem as making bleaching powder, the same difficulties have to be overcome; so it need not be discussed further.

Mr. Crookes's sodium amalgam for making the mercury ready to seize any particles of gold, and to keep it from getting "sick," can be replaced by making the mercury itself the cathode. It is questionable whether this would be worth while, as the sodium amalgam is very convenient.

Mr. Crookes has recently brought out other electric gold processes. He finds that the particles of gold become amalgamated, and collect and get caught in the mercury, if the stamped quartz is washed in a weak solution of a mercury salt, under the influence of an alternating current of small frequency. It is difficult to see how the alternating current works. Unless the current-density or the resistance of the electrolyte is something fabulous, there cannot be any current in the small particles of gold, as the minutest polarisation would make all the electricity flow by the electrolyte, and not by the little pieces of gold, even though they are very much better conductors.

(To be continued.)

ON THE EFFICIENCY OF TRANSFORMERS.*

BY M. VON DOLIVO-DOBROWOLSKY.

Since the distribution of electricity by high-pressure currents has lately again come into prominence, thanks chiefly to the practicability of the transmission of power by means of alternating current and the "Drehstrom," it has become necessary for us to know something more about transformers. I do not mean to imply that too little has been written about transformers, or that there has been too little experimenting; on the contrary, a great deal may be found regarding the possible distortions of the current curve owing to Foucault currents, and we hear of very exhaustive experiments as to whether hysteresis, in spite of constant magnetisation, does not really vary slightly according to the load on the transformer. But as to how this apparatus is to be proportioned in order to work economically—which is the main idea the electrical engineer must keep before him if he proposes to give the transformer a really practical and efficient form—little enough is to be found amongst the mass of written material. This has given rise to many entirely false principles, ideas, and prejudices, which have come to us from early times, and are now difficult to eradicate. I am not, as will be apparent to you, by any means an adherent of all the Swinburnian deductions; but I must, to be just, allow Mr. Swinburne the merit of having paved the way towards the practical consideration of transformers. I cannot, of course, in this Paper propound a complete theory of what I hold to be the proper construction of transformers, but I will select just a few heads and communicate them to you.

I have already briefly described my fundamental theory of the alternating current at the Electrical Congress held at Frankfort. I said: The magnetism (reckoned as number of lines of force) rises so high that the electromotive force induced in the apparatus, added to the loss of potential, becomes equal to the exciting potential. If B be the number of lines of force, p the number of periods, N the number of turns on the coil, and E the so-called mean electromotive force* in volts, we get the known equation,

$$E \times 10^8 = 4\,p\,N\,B.$$

If, however, firstly, the loss of potential be very small, as is the case with transformers and motors; secondly, the number of alternations remain constant; and, thirdly, the apparatus be ready wound (that is, the number of turns be fixed), the above formula becomes simplified, as follows:—The magnetism is equal to the terminal potential multiplied by a constant. In other words, the potential is a measure of the magnetism, and *vice versâ*.

This formula is applicable generally, without regard as to whether the coil generates current or receives it, or whether the current be strong or weak (the latter statement is, of course, only correct in respect of a small loss of potential); and, further, whether the magnetism be generated from some external source, or induced by the current itself flowing through the coil. Neither has the value of the magnetic resistance any effect. If the windings and alternations remain constant, the magnetism for a certain potential is always the same; and it may be said that magnetism and potential mutually balance each other. As a consequence of this, every essential difference between induction, self-induction, mutual induction, &c., ends.

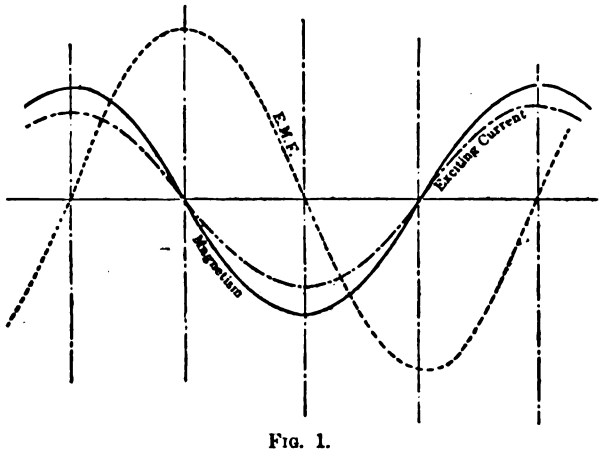

FIG. 1.

As the electromotive force is proportional at any moment to the rate of change in the number of lines of force, the latter being greatest at the moment of inversion of polarity, we have the further important rule, that the phase of the electromotive force (or potential) lags behind the phase of the magnetism by a quarter period. (*See* Fig. 1.) So long as the current is only a magnetising current, or merely has to furnish the proper number of ampere-turns without performing further work, it cannot be otherwise thought of than in connection with the lines of force which it induces; the phase of the current then coincides with the phase of the magnetism. If we examine the curve in Fig. 1 more closely, we see that the current flows half the time *with* the potential, the other half *against* it. Our coil is, therefore, half the time an apparatus absorbing energy, and half the time an apparatus generating energy. On the whole, therefore, the current neither delivers nor absorbs energy; it is "wattless." This "wattless" current, since it only serves to create a magnetic field without doing any work, we will call "exciting current." If, on the other hand, current is passed through a non-magnetic apparatus, that is, one in which resistance only has to be overcome and no magnetic field exists or is created, heat is developed all the time, according to Joule's law; the current pulsates, then, in synchronism with the terminal potential. This is the real "watt current." Neither the "watt current" nor the exciting current exist as such alone; they are invariably combined, for every current creates a magnetic field, and there are neither non-inductive resistances nor coils without resistance, and an ideal soft iron without residual magnetism has yet to be discovered. Every alternating current consists, practically, therefore, of two currents, the watt current and the exciting current; while we must add together as two forces acting at right angles to obtain their resultant. Fig. 2 shows the addition of the exciting current O C_1 to the watt current O C_2, where O C is the resulting

* A Paper read before the Electrotechnic Society of Berlin, March 22, 1892.

* The effective electromotive force is, as is generally known, some 10 per cent. higher than the mean.

Digitized by Google

current as measured in practice, and is then the angle of lag of the resultant current behind the terminal potential or electromotive force. With high potentials or with rapid alternations the electrostatic capacity, or the electrostatic field, must not be neglected. Here again we have a wattless so-called "charging" current, only that in this case the terminal potential is a quarter of a period behind the current; or, what is practically the same thing, the current is accelerated a quarter period ahead of the terminal potential. Strictly speaking, therefore, every alternating current resolves itself into three currents: the exciting current, the charging current, and the watt current. I shall in my remarks to-day leave the capacity phenomena mostly out of the question, as they only come into play in special cases.

A great deal may be adduced already in respect of transformers from the above-mentioned formulæ; and I take the following by way of illustration.

(1.) The magnetism of a transformer remains almost absolutely constant under all loads; it decreases only in proportion as the loss of potential in the primary, that is, the exciting coil increases; and then only 1 or 3 per cent. It therefore follows again that hysteresis, that is, the demagnetising work in the iron core, is

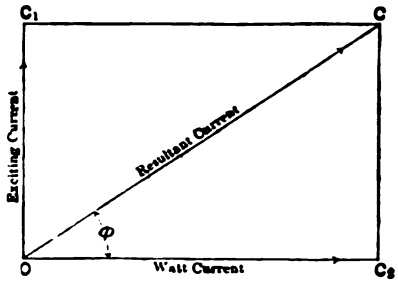

Fig. 2.

an almost constant quantity; at any rate, this change is of no importance in considering the efficiency of the transformer, since it is practically of no importance whether we assume that the transformer consumes 2·00 or 2·02 per cent. of the full load as exciting current.

(2.) In an unloaded transformer the watt current is very small, as only the demagnetisation of the iron and the minimum potential loss in the copper call for an expenditure of energy.

(3.) The current of a transformer on open circuit consists, for the most part, of the wattless exciting current, and is, consequently, dependent upon the magnetic resistance. The resistance of the iron necessitates more or less ampere turns for the magnetism required by the terminal potential; the given or assumed number of turns will then give the maximum ordinate of the exciting current.

(4.) Upon plotting the diagram shown in Fig. 2 it will be found that, owing to a small current, the exciting current causes a considerable lag of the resultant current. This lag and the strength of the resultant current are greater the greater the ratio of the magnetic resistance (that is, the necessary number of ampere turns) to the primary turns. In the case of transformers having many turns per unit difference of potential (that is, with much copper) the exciting current, for reasons which will be shown later, and for the above reasons, is smaller, even when small magnetic resistance is not specially taken into consideration.

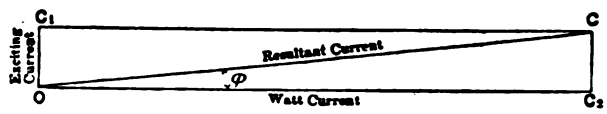

Fig. 3.

(5.) If a transformer is loaded, and especially by incandescent lamps or other approximately non-magnetic resistances, only that component which I have called the watt current arises; and the phase difference, therefore, diminishes. Fig 3. shows that, even if the exciting current amounts to as much as 10 per cent. of the maximum working current, we have at full load practically no difference between the resultant current and the watt current; that is to say, between apparent and real watts. In fact, the angle here is only 6deg., the cosine of which is 0·985, and consequently the difference between the real current and that determined by measuring the watts is only 1½ per cent. In most transformers the exciting current is far below 10 per cent., so that with incandescent light distribution the lag in the transformers need not be taken into account as all.

(6.) If, as in the case of open-circuit transformers, the exciting current is large compared with the cross section of the copper, the Joule loss even at no load is not to be neglected; this results in a larger watt current component than would ensue from hysteresis losses alone. Such, for instance, is the case with Mr. Swinburne's "hedgehog" transformer, where the exciting current amounts to about 30 per cent. of the maximum watt current. Nevertheless, its consumption of watts at no load amounts to only 1 per cent. of its full output.

(7.) If a transformer has a load of coils, or similar magnetic apparatus, it will deliver an exciting current principally. The consequence is that only the exciting current rises, and there is no diminution of lag. The diagram in Fig. 2 is always applicable, and the transformer connected between the generating station and the point of consumption will only add its own exciting current and its own watt current required for the internal losses.

(8.) It is possible by augmenting the magnetic resistance of the transformer—as, for instance, by means of the insertion of paper between the joints of the iron (Fig. 4)—to increase the exciting current in order to compensate for the inverted phase difference caused by the electrostatic capacity of the circuit. In this way the current generated in the dynamo may be reduced to a minimum in comparison with the consumption of watts.

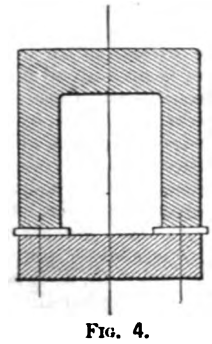

Fig. 4.

Having sketched in the above remarks the theory of the transformer according to modern ideas, I proceed to the question of design. A best method for transformer calculations can no more be given than in the case of dynamos. As in the latter case, the best thing to do is to sketch on paper a number of transformers, make your calculations, and then select that which best meets the case in question. If we consider certain leading principles from the very beginning, we may by practice develop the instinct so far as to rapidly hit upon the desired dimensions without wasting too much paper. Curves are very valuable in the case of the design of a transformer intermediate between two stock patterns. Having sketched a transformer, we submit it to the following most important calculations. In the first place, we have to see that the copper resistances are sufficiently small, which is an easy matter. Then, if no alterations in the copper cross-section are necessary, we calculate the energy consumed in reversing the polarity of the

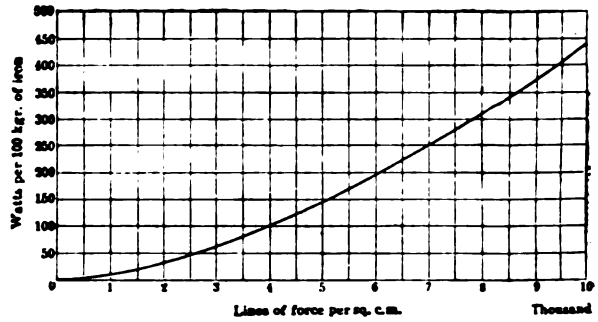

Fig. 5.

iron. It is one of the most difficult problems in transformer construction to get little loss of energy in the iron and at the same time to provide sufficient room for the winding. The energy absorbed by polarity reversals depends chiefly upon what is now called hysteresis; but to hysteresis loss must also be added the Foucault current losses, which are never entirely eliminated; these are, however, very slight with properly laminated iron; at least, I have found it so from a study of the curves of total iron losses with various magnetic densities and various frequencies. The watt loss by hysteresis with a certain magnetic density is just proportional to the mass of iron, and is also nearly proportional to the number of alternations (a very slight increase is due to Foucault currents). So far as the dependence of the hysteresis loss (Polwechselarbeit) upon the magnetic density is concerned, I have almost invariably found a pleasing accordance with the law enunciated by Mr. Steinmetz, of New York, as well as with Prof. Ewing's curve. I should say at once that the numerical factors vary according to the quality of the iron. From an examination during the last two years of nume-

Digitized by Google

rous samples of sheet iron of the Allgemeine Electricitäts Gesellschaft I have got values which were 1·2 to 2·5 times greater than those given by Prof. Ewing. Although better kinds of iron are not excluded, yet I believe that in general practice Prof. Ewing's figures should be multiplied by 1·6 to 1·7. The curve in Fig. 5 shows us the loss per 100 kilogrammes in a moderately good iron with 80 alternations (40 periods), and with various magnetic densities. The figures of this curve are 1·7 times greater than those of Prof. Ewing. A fairly proportionate difference may be assumed for frequencies, not differing too widely from the above.

(To be continued.)

THE BRITISH ASSOCIATION COMMITTEE ON ELECTRICAL STANDARDS.

The following communication has been made by Dr. Oliver Lodge to the above Committee :—

In view of the hoped-for presence of Prof. von Helmholtz and other distinguished foreigners at this year's meeting of the British Association in Edinburgh, it will probably be recognised as suitable to take up and continue the discussion on new electro-magnetic units for practical purposes, which was begun last year at Cardiff. I therefore beg to contribute the following notes, and to conclude by moving some resolutions.

One great fact brought into prominence by the practical development of electricity is the analogy or reciprocity between the electric and the magnetic circuit, and this is the fact which it behoves us to emphasise in the naming of fresh units. The magnetic circuit has as yet no authorised names applied to it. The electric circuit is well provided, but perhaps one or two improvements can be made.

(1.) The Electric Circuit.

The first point on which I consider that practical men would do well to insist is that names shall be given to the complete things dealt with, rather than to mere coefficients. Thus of all units with which they are concerned there can be no doubt but that *volt* and *ampere* are the most prominent. These are the active things with which electrical engineers have to deal, and these are the things for which meters exist on every wall in an electric lighting station. The ohm, or unit coefficient of resistance, is comparatively academic in character ; it is a constant of a coil of wire or of an underground lead, it is nothing vivid and active. The engineering use of the term ohm is mainly in connection with insulation and other high resistances ; for large conductors the equivalent "volt per ampere" is perhaps more often used. It is the drop of potential which a given conductor entails for a given current that is of real interest to an engineer, and it is this of which in large leads he consciously thinks.

A 6-ohm conductor means one that drops 6 volts for every ampere that is sent along it. If you send 3 amperes along such a line, the potential at the far end is 18 volts below that at the near end. The clear realisation of this fact would be almost aided by the complete title, 6 volts per ampere, instead of the abbreviation, 6 ohms. Nevertheless, the name ohm is in common use and hence may be assumed useful.

A still more useful name, however, for good conductors would really be the reciprocal of an ohm—the ampere per volt. Suppose this called a mo, as Sir W. Thomson once suggested, then a cable of 20 mos would be one that conveyed 20 amperes with a drop of 1 volt. A thousand-mo cable would convey 500 amperes with a drop of half a volt, and so on. It is more directly practical to think of the amperes conveyed per drop of voltage, than of the drop of voltage per ampere. I believe that some authorised name for unit conductance would be welcomed.

Units of Inconvenient Size.

The authorised name "coulomb" for unit quantity is barely used by engineers, who are content with ampere-hour ; thus proving that what is needed in practical units is not so much a consistent decimal system, as a set of units each of practicable magnitude.

Farad.

The effort after consistency has resulted in the useless "farad" ; and this should be a lesson not to try and fix units of unreasonable size. The C.-G.-S. units already exist as a consistent system ; the only objection to them is that they are of unpractical size. The whole object of devising a practical system of units was to have things of every-day size to deal with. The volt, the ampere, and the ohm satify this condition. The coulomb, the farad, and the watt do not. Already they have practically given place to the ampere-hour, the microfarad, and the kilowatt.

Considerably more progress would have been made in knowledge of ordinary capacities if the microfarad had been called the farad, so that easy submultiples of it would have been available to express the capacity of Leyden jars, and such like things. The capacity of an ordinary jar would then have been a few millifarads, and a microfarad would have been the capacity of a short bit of connecting wire. I ask whether this change would introduce serious confusion even now. I think not. Nobody cares the least about "coulombs per volt," and so there is no sense or use in the present farad. Telegraphists would surely soon consent to drop the useless prefix micro ; and the factor of a million is too great to render doubt possible as to what was intended, even in the transition stage. It ought to be regarded as essential to have the practical unit somewhere not hopelessly away from the middle of the range of probable multiples and submultiples.

Coulomb.

A coulomb again is almost useless as a synonym for the ampere-second ; it is so easy to speak of ampere minutes or ampere hours. If the name coulomb could be set free from its present superfluous meaning it could usefully be applied to the electrostatic unit of quantity, which wants a name. Teachers would find it convenient at once, and in the apparently imminent line of development engineers might find it useful before long. It is the charge on a two centimetre sphere at a potential of 300 volts (or on a one foot sphere at 20 volts). The capacity of the two-centimetre sphere would be $\frac{9}{10}$ of a (new) microfarad.

Watt.

Lastly with regard to the watt. The name volt-ampere is almost as good as the name watt, especially since the watt is also one joule per second.

Both names, watt and joule, are not really wanted by electricians, to whom their co-existence is rather confusing. I believe it would be more convenient to use the term watt in the sense it gets so frequently used now, viz., energy, say a volt-ampere hour ; in which case a kilowatt would be synonymous with the present Board of Trade unit.

The rate of working, or power, could then be expressed in a rational and unforced way as so many watts per hour or so many volt-amperes. It is much more natural to give a name to a definite thing like a quantity of energy, than it is to give it to a mere rate of working. The latter is instinctively felt to need a reference to time ; just as a velocity unit has not been practically found to need a name, being quite simply expressible in feet per second or miles per hour : and even when a name has been given, like "knot," instinct constrains people to practically get rid of it again by speaking of knots per hour, just as we find "kilowatts per hour" already often used in electrical workshops. I suggest, therefore, that the present watt is too small, that it is sufficiently expressed by a joule per second, and that it would be more useful if magnified 3,600 times, and turned into a unit of energy.

That we should thus have several energy units—the erg, the joule, and the watt, all of quite different sizes, is no objection, but an advantage, seeing the extreme importance of energy. Such things as length, mass, time and energy demand a fair range of units. It would be tedious to express centuries in seconds.

(2.) Magnetic Circuit.

In speaking of the magnetic circuit I wish to refer back to my opening remarks concerning the electric circuit, and the class of things for which names should be found. In the magnetic circuit the only thing at present seriously attempted to be named is, in accordance with the historic parallel of the ohm, a coefficient or characteristic of a coil of wire—its coefficient of self-induction ; the unit of which has been called variously a secohm, a quadrant, and a henry.

Total Induction.

But the real active thing with which engineers are concerned is total magnetic induction, total number of lines of force across an airgap : as between the polepieces or through the armature of a dynamo, or in the circuit of a transformer. It may be called the electro-magnetic momentum per turn of wire ; or the surface integral of **B**. This total induction is in some respects analogous to electric current, and has occasionally been called magnetic current (a bad name), or "magnetic flux." It is, however, more strictly analogous to the coulomb, and its time rate of variation is the more proper representative of electric current. Its common practical name at present is "total lines," or "total induction," or "number of lines."

Now "one line" is awkward as a unit, besides being (if a C.-G.-S. line) inconveniently small. The earth, for instance, sends 4,400 such lines through every horizontal square metre about England ; through a square inch it only sends a fraction of a line. A practically sized unit of induction badly wants a name, and "henry" would have done for it very well, and have been both more suitable and more useful for the actual quantity than for a coefficient. But "henry" has already been half appropriated to the secohm, so, for illustrative purposes at any rate, I propose to use the name "weber" for the unit magnetic flux.

Digitized by Google

Concerning the most convenient size for the weber, there is much to be said for making it 10^8 C.-G.-S. lines, though that is bigger than ordinarily occurs in practice; because then a wire which cuts one weber per second will have a volt difference of potential between its ends. Or a coil of 20 turns through which the magnetic induction changes at the rate of one weber per second will have an E.M.F. of 20 volts induced in it. The average E.M.F. in such a coil, spinning 30 turns a second, and enclosing a maximum total induction of one weber, is 600 volts.

This is the dynamo use of the unit; the following is the motor use:—A wire carrying an ampere and cutting a weber per second, does work at unit rate, viz., one joule per second.

Probably the simplicity of all this compensates for the rather unwieldy size of the unit. A strongly magnetised piece of iron may have 20,000 lines to the square centimetre; so a weber could occur across a narrow air-gap half a square metre in area. The earth gives an induction of about one weber through every 23,000 square metres of England, or 100 webers per square mile. The earth induction through a horizontal square metre is 44 micro-webers, so with micro- and milli-webers the range would be fairly covered; though a smaller weber would have been better if it had been equally convenient as regards the volt. The pull between two parallel surfaces joined by a weber is $10^{16}/6\pi$ dynes, or 400,000 tons. A milli-weber gives less than half a ton pull; and a micro-weber less than half a gramme.

Because of the property that the voltage excited in a circuit is equal to the webers cut by it per second, a weber might be called a sec-volt. It is equal to a secohm-ampere-turn; that is to say, if a single turn of wire can have a self-induction coefficient of one secohm, it will excite a weber of induction for every ampere passing through it.

[Such a circuit in the form of an anchor ring would be enormous, something like a mile across; but it could be made in the form of a solid cylinder of best iron ($\mu=2,500$), with an axial perforation for the wire, and 80 metres long. If a secohm coil has n turns, then an ampere passing through it excites only $1/n$th of a weber; for, since every turn encloses the induction, the latter is effective n times over, and so the induction coefficient is n times the induction per ampere, or n^2 times the induction per ampere turn.]

No name is needed for intensity (or density) of induction (B), for that can always be expressed in webers per unit area. [For instance, strongly magnetised iron, with say 10,000 lines to the square centimetre, has one-tenth of a weber per square foot, or 0·7 milli-webers per square inch.] And there is a practical gain in thus leaving the specification of area open, for it enables British units of length to be employed in measuring air-gaps, yokes, cores, and pole-pieces. So long as dynamo dimensions are commonly expressed in inches, there is no serious objection to specifying induction in fractions of a weber per square inch or per square foot.

Magnetomotive Force.

Now, consider the magnetic analogue of the volt; the unit of magnetic potential or magnetomotive force. By this is understood the line integral of the magnetising force H, the quantity $4\pi nC$, the step of potential once through and all round the circuit of a coil. It is a quantity most important in practice, and requires a name.

Mr. Heaviside has suggested the name "gaussage," as analogous to voltage; and, if this were adopted, the unit of magnetomotive force would be the gauss. The intensity of magnetising force would be the gauss-gradient, or drop of gaussage per centimetre; no special name is needed for the unit of this quantity H.

The common practical unit of "gaussage," at present is the ampere-turn, and this has several advantages. It may, however, be found better to make some convenient number of ampere-turns into a gauss; for instance, the C.-G.-S. unit of gaussage would be $4\pi/10$, or, 1·2566 ampere-turns. If that were adopted as the gauss, the horizontal component of the earth's magnetic intensity about here would be, say, ·18 gauss per linear centimetre.

But this unit, whether the C.-G.-S. unit or the ampere-turn, is very small. The step of potential all round a single ampere-turn is only equivalent to a vertical step of about two centimetres in the earth's field. Nevertheless, in spite of its smallness, the ampere-turn as practical unit of gaussage will probably commend itself by reason of its simplicity. Let us see how it works out.

Reluctance.

The ratio of gaussage to the induction excited by it is a quantity characteristic of the magnetic circuit, and called its reluctance or magnetic resistance. This is the quantity $l/A\mu$ for simple circuits, or $\Sigma\, l/A\mu$ for complex ones; it is unfortunately not constant for any but air circuits. This constitutes one difficulty of naming its unit satisfactorily, else it might be expressed as so many "gilberts" or "sturgeons" (analogous to ohms). It is, however, fairly constant under many common conditions of practice, and it can always be expressed as gausses per weber; and perhaps this way is sufficient.

A magnetic circuit with unit reluctance is one that requires one gauss to induce in it one weber.

Permeability.

Permeability (μ), analogous to electric conductivity, would be measured by the webers induced through unit cube of the material between whose faces there is unit fall of gaussage. It has been suggested (by Prof. Perry) that the permeability of air had better be called $4\pi\times10^{-9}$. But the whole electro-magnetic system of units is based on the μ for air being called 1; so it would be rather confusing to change that. Moreover, it would be a retrograde step to affix another incorrect value to the constant μ, instead of waiting and trying to find out what its value really is. It is better to adhere for the present to the existing table of permeabilities, and to use whatever constant factor may be needed in order to turn $l/\mu A$ into practical units of reluctance.

Permeance.

But the reciprocal of reluctance, or the webers induced per gauss, may be the more instructive thing to attend to and name; just as conductivity is often more directly interesting than resistance. This reciprocal ratio, $\mu A/l$, has been called "permeance," and that is not a bad name for it; it is proportional to the inductance of a single-looped circuit. Permeability is the permeance of unit cube of the material. Permeance is the webers induced per unit drop of gaussage. Permeability is the webers per unit area induced by unit gauss gradient.

The permeance of the magnetic circuit enclosed by a solenoid of wire is the same as its appropriate self-induction-coefficient divided by 4π times the square of its number of turns. The C.-G.-S. unit of permeance (or of reluctance) is that of a centimetre cube of air, and is not a bad-sized unit. But it is inconsistent with the weber as 10^8 and the gauss as a single ampere turn. One of the three must give way.

On the whole, I have no hesitation in suggesting that the derived unit (that of permeance) must give way, and be taken as $4\pi\times10^7$ C.-G.-S. units, in order to harmonise with the other two, as already defined.

The fact is that the great size of the weber renders a small gauss desirable, in order that their product may not represent too large a quantity of energy. For instance, if 1 C.-G.-S. unit were taken as the unit of permeance, the weber being fixed at 10^8, then the gauss would also be 10^8, and the gauss-weber would be 10^9 joules, or nearly 300 Board of Trade units; which is far too much. Whereas if the unit of permeance is fixed high, and the gauss kept small, then the energy corresponding to a gauss-weber may be moderate. Thus with 10^8 C.-G.-S. as weber, and an ampere-turn as gauss, their product is only $10^9/4\pi$ ergs, or $100/4\pi$, or about 8 joules; which will be useful in energy considerations connected with the heating of transformers.

I therefore propose, in order to retain the ampere turn as unit of gaussage, that the permeance of a cylinder of material of length l and area A be reckoned as $\mu A/l$ multiplied by $4\pi\times10^7$, if dimensions of the cylinder are measured in centimetres; μ being its ordinarily tabulated value with air=1. If dimensions are measured in inches, then the permeance of a cylinder will be $\mu A/l$ multiplied by $4\pi/2{\cdot}54\times10^7$, that is by about $\frac{1}{2}\,10^8$. The unit of permeance thus suggested is immensely big, and it requires a name of which easy sub-multiples could be formed. A slab of iron one centimetre thick, and with its $\mu=2,500$, would need an area of five square metres in order to have unit permeance; but a micro-unit would be possessed by an air-gap a millimetre thick and less than a decimetre square.

Proposed Resolutions.

1. That the unnecessary prefix "micro" be dropped before the word farad, and that the farad be defined afresh as 10^{-15} C.-G.-S. electro-magnetic units of capacity.

2. That the name "mo" for the unit of conductance, or the ampere per volt, be recognised and adopted. (Every *mo* in a cable enables it to carry an ampere with a drop of 1 volt.)

3. That the ampere-hour be recognised as a convenient practical unit of electrical quantity.

4. That the volt-ampere-hour be recognised as a convenient practical unit of electrical energy, and be called the watt. (It equals 2,640 foot-pounds, or a trifle over a foot-ton.)

5. That the present Board of Trade unit be called a kilowatt.

6. That the ordinary unit of power be a kilowatt per hour. (It equals about four-thirds of a horse-power, more accurately 1000/746 H.P.)

7. That it is convenient to retain the name joule in its present sense of a volt-coulomb, or ten million ergs, for use in the science of heat; since heat-capacities are conveniently expressed in joules per degree; and it will be handy to remember that a volt-ampere generates one joule of heat per second.

8. That the name coulomb be affixed to the electrostatic unit of quantity (for academic purposes).

9. That a name be given to unit magnetic flux or total induction, and that the name weber is suitable.

Digitized by Google

10. That the most convenient size for the weber is 10^8 C.-G.-S. units or "lines" (since the rate of change of this through a circuit is equal to the induced voltage).

11. That a name be given to unit magnetic potential or magnetomotive force, and that the name gauss is suitable.

12. That the handiest size for the gauss is one ampere-turn.

13. That a name be given to the ratio of the weber to the gauss, or unit of permeance, or self-induction per turn of wire. [If the above resolutions were adopted, this unit would be $4\pi 10 \times {}^7$ C.-G.-S. units, or $\frac{1}{8}$ secohm per turn.]

14. That intensities of field be expressed in gausses per unit length, and densities of induction in webers per unit area (leaving the length or area unit open for practical convenience to arrange).

No doubt many of these recommendations have been made before. Mr. Preece has often urged the change of farad, so that I hope there will be no difficulty about that. I find that my magnetic suggestions are very similar to those suggested by Prof. Perry in his modified letter to the Committee as published in *The Electrician*, Vol. XXVII., p. 355 (July 31, 1891), and received there with approving editorial comments. The accordance between our suggestions is satisfactory, and makes it likely that they are such as engineers may be satisfied with and be willing to adopt. I need hardly say that I lay no stress upon the particular names here proposed. In choosing them I have been influenced by such trivial considerations as the selection of a monosyllable to correspond with volt, and a dissyllable to correspond with ampere or coulomb.

[With regard to Prof. Perry's footnote concerning college instruction and use of C.-G.-S. units, I suppose systems of teaching differ; but a senior student ought to be taught to deal with concrete quantities in so familiar a manner that no possible admixture of units can be any puzzle to him, nor involve anything worse than a little tiresome arithmetic.]

Mechanical Units.

There are several quantities in dynamics beside the joule and the watt for which brief names would be advantageous. I do not propose to discuss these fully now; but the present opportunity might be utilised by agreeing to at least one unit, that of pressure, viz., the "atmosphere," which might be defined as 10^8 C.-G.-S., or dynes per square centimetre, and stated to be equal to the pressure of a column of mercury 75 centimetres high at a specified temperature. The inconvenient pressure, 76 centims., might be spoken of as a Regnault atmosphere. I believe that a smaller unit of pressure, for instance, the micro-atmosphere or "barad," might also be usefully named. These pressure units will be useful for expressing energies per unit volume also, and the "barad," or whatever other name is decided on for the erg per cubic centimetre, is of reasonable magnitude for many purposes.

SOME SEPARATIONS BY ELECTROLYSIS.*

BY E. F. SMITH AND D. L. WALLACE.

This Paper contains an account of work done at the University of Pennsylvania, in continuation of the authors' experiments on electrolysis, which have already been published (*Ann.* Chem. Pharm., 13, 417, and *Proc.* Chem. Soc. Fr. Inst., 3 20), which showed that a perfect separation could be effected by the electrolysis of a solution of the double cyanide of gold. The experiments recorded were undertaken in order to determine the effect of the presence of an excess of potassium cyanide. The temperature was found to have an important bearing on the rate of deposition of the gold, and the authors reserve the study of this for a future investigation. In the case of arsenic, the presence of a large quantity of potassium cyanide hinders the deposition of the gold, and on increasing the strength of the current arsenic is deposited with it. If, however, the solution is in about the following proportions, viz.: 10ccm. chloride of gold solution (=0·1240grm. gold), 10ccm. arsenic solution (=0·1000grm. arsenic), and 0·75grm. potassium cyanide in 150 water, results accurate enough for all ordinary analyses are obtained, and the deposit is free from arsenic. Similar results were obtained in the case of molybdenum, and of tungsten if the tungstic acid was first dissolved in potassium hydrate, and then added to the gold solution. The separation of gold from osmium, and of the latter metal from cadmium, silver, and mercury, is also readily effected in a corresponding solution; but in the case of cadmium, if very accurate results are required the amount of cyanide of potassium must be reduced. Since the deposition of gold was found to be checked by the addition of caustic potash to the bath, while that of silver was unaffected, this appeared to afford a means of separating these two metals, but experiment showed that they plated out together from a mixed solution. In the case of cadmium and nickel, however, the addition of caustic potash enables a separation to be effected electrolytically. The electrolysis of a solution of gold in ammonium sulphide gave too low results, and an attempt to separate gold from tin in a similar solution failed. The currents employed are described as liberating from 1·8 to 2 ccm. of mixed gases per minute, but the temperature and pressure are not stated.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

New York, *July* 22, 1892.

The Electrical Utilisation of Water-Power in California.—A remarkable power plant is now in process of construction in San Antonio, South California. The plant is located in the San Antonio Cañon, where there is a minimum fall of 1,300 cubic feet of water per minute, and an available head of about 400ft. The power is brought to the power station through 1,900ft. of 30in. and 600ft. of 24in. double riveted sheet iron pipe, which involves a loss of head by friction of 12ft. The laying of the pipe necessitated a rock channel 1,300ft. in length, as well as several heavy open cuts. The power station is provided with four double nozzle Pelton wheels 34in. in diameter, coupled direct to the armature shafts of the same number of Westinghouse alternating-current generators of 200 H.P. each. The wheels will run at 600 revolutions per minute. Two exciters are provided, which are also run by Pelton wheels coupled to the shafts in the same manner. The current is carried on two No. 7 bare copper wires seven miles down the cañon to a point where the lines diverge, one running to Pomona 15 miles distant, and the other to San Bernardino 26 miles, covering by the return circuit in the latter case a distance of 56 miles. By means of transformers the potentials will be raised at the generators to 10,000 volts, and the current will be carried at this pressure to sub-stations located just outside the cities, where by means of step-down transformers the pressure will be reduced to 1,000 volts, and will then be distributed for both light and power purposes. The motors used will be of the Westinghouse synchronous type.

The Niagara Falls Projects.—Not much has been heard for some time of the company that is at work preparing to utilise a part of the Falls of Niagara. It was announced last week, however, that the Canadian Niagara Power Company, which was organised to develop the power of the Horseshoe Falls in Victoria Park on the Canadian side, had already met and elected officers. The last of the exclusive privileges to develop the power of the Falls in Victoria Park, which was granted to Messrs. Shaw, Stetson and Rankine by the Park Commissioners, was transferred to the newly organized Company. Col. Shaw, who is at the head of this company, says that it is their intention to await the completion of the tunnel on the American side before beginning operations on the Canadian side. It was announced some time since that the Canadian rights had been bought up by the Cataract Construction Company, and were now under the control of the same parties, who were working on the American side. It is understood that the water wheels for the plant on the American side were selected some time ago, and will be installed by a foreign firm. The dynamos, however, have not been selected and the Company is still seeking to find the cheapest, and at the same time the best character of plant to instal for this huge transmission scheme.

Electricity at the Chicago Exhibition.—There seems to be very little news nowadays about the electric exhibits at the World's Fair. The allotment of space has not yet been made, and the work of finishing the building is going on as rapidly as possible. Now that the contract for lighting the buildings has been let to the Westinghouse Company there is considerable speculation as to what character of plant will be installed and how satisfactory the equipment will be. It is reported that the Westinghouse Company, intend to build a machine that will supply 20,000 16-c.p. lamps and several having a capacity of 10,000 lamps, and it is said to be their intention to build the 20,000 lighter to be driven by direct connection with a pair of compound engines without fly-

Digitized by Google

wheels. Regarding the wiring for the Exhibition lighting plant, it is said that the rules require that all transformers shall be placed on the outside of the buildings, in the case of the Liberal Arts building, which is 8,800ft. wide, 1,600ft. in length, to say nothing of the height, so that it will require some very extensive secondary wiring, and the cost of secondary leads for this building alone will call for an immense expenditure on copper. Of course the General Electric Company controls the three-wire system so completely that it will be impossible for the Westinghouse Company to instal any of its lights by the use of that method of distribution.

Mr. Cyrus Field.—It is a pleasure to know that several months before his death Mr. Field presented to the Museum of Art in this city his entire collection of medals and paintings relating to the laying of the Atlantic cable. The condition of the gift was that the articles be kept together in an alcove of the Museum, and so arranged that they would be easily accessible for inspection.

GERMAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

The commercial controversy between the advocates of the alternate-current and of the battery system of distribution is at present raging as furiously in Germany as it was a few years ago in England. But there is one thing which distinguishes this German controversy from the English one, and that is firstly the mass of valuable data which is brought to light, and which up till now has been kept secret; and, secondly, the almost abusive language that is used. Some time ago there appeared a pamphlet, written by Herr F. Ross, manager of the Helios Company of Cologne, entitled, "How Shall We Build our Electric Central Stations?" The author, after some introductory remarks, went on to show how low the working efficiency of some battery stations really was, and then chanted a hymn of praise on the alternate-current system, forgetting to give any results of actual work. This somewhat impolitic pamphlet was answered a week or so ago by a very angry one from the Hagen Accumulator Works; and to the attacks of this pamphlet Herr Ross has just answered by "Once more, How Shall We Build our Central Stations?" From these three pamphlets I will try and pick out some data which may be of interest.

The works at Hagen, which manufacture the Tudor cells, have a large battery at the Barmen station, which is only a few miles away from Hagen. At this station the total efficiency as calculated from the official records of the station manager was

Before the plates had been changed (from May 1st to May 10, 1890) ..... 37 per cent.
After the plates had been changed (from Sept. 20th to Sept. 28th, 1890) ..... 55·8 ,,

At the Darmstadt station the real watt hour efficiencies were 38·6 per cent. in 1889, and 55·9 per cent. in 1890. The battery was reconstructed at the end of August, 1889, as internal short circuits had brought the efficiency down to a very low figure, which in May, 1889, is alleged to have been 16 per cent. To this the contractors answer that at Darmstadt the battery only serves as an auxiliary means for lighting the safety lamps of the theatre four times a week and for feeding a few private lamps during the late hours of the night. This objection is a sound one, for the Darmstadt station was intended for 6,000 lamps in all, and 7,000 are now connected to it; but of these nearly 1,000 are in the Ducal Palace, where they are only used for festivals, and 2,000 or so are in the theatre, which is open four times a week. The Hagen pamphlet then goes on to assert that the working efficiencies of the following stations are as stated below:—

Dessau, 1890.....	78·9 per cent.	Hanover, 1891	78·7 per cent.
Dessau, 1891.....	79·37 ,,	Kensington Court ..	85·3 ,,
Barmen, 1891.....	70·2 ,,	Davies Street	82·94 ,,

To these overpowering data Herr Ross coolly answers that the splendid results of the last two tables were obtained with Crompton-Howell and not with Tudor accumulators, and besides that the efficiency of the Barmen battery, though it was raised to 70 per cent. as an average value, was somewhat low even in some months of 1891, being only 56·85 per cent. in February of that year, according to the contractor's own showing. Herr Ross concludes by detailing the balance-sheet of the Cologne central station, as he received it from the Director of the Cologne Gas, Electric, and Water Works (Herr Francis Poly). But be the merits of the case what they may, the unfortunate fact remains that on June 28th the Barmen Central Station Committee had to vote a further 30,000 marks for a second renewal of the battery.

The report which Mr. W. H. Lindley and Herr Oscar von Miller have presented to the Frankfort Municipality with regard to the electric lighting of that fine city forms an elaborate volume. The two learned authors first of all studied the question whether continuous, alternating, or polyphase currents should be employed. Three schemes have been worked out—(i.) alternate current and transformers; (ii.) continuous current with accumulator sub-stations, the accumulators being charged directly; (iii.) continuous current with sub-stations, where the accumulators are charged by means of rotating commutators which transform alternating into continuous currents. The schemes assume a total load of 67,000 16-c.p. lamps, or their equivalent. The central station is placed near the Main. The conclusion ultimately come to is that for Frankfort the most favourable system of distribution would be the alternating-current transformer system. Herr von Miller is also working out a plan for a central station at Strasburg, which town has also invited tenders for an electric railway from the Thomson-Houston Company.

The great event of the past few weeks has been the great and unexpected reduction in the price of the 16-c.p. glow lamps from 1s. 6d. to 1s. Two or three months ago a private consumer thought himself fortunate in getting his incandescent lamps for 1s. 8d. I am not quite aware what has caused this reduction, but I think the first who commenced it were Messrs. Siemens and Halske of Berlin, and of course the other manufacturers had to follow suit. But now that the private consumer is getting cheap lamps, he is also being overwhelmed with pamphlets, filling his innocent mind with doubts and monstrosities such as 2-watt lamps, 1½-watt lamps, short life, high efficiency, blackening, increase of resistance, decrease of lighting power, &c., &c. Messrs. Siemens and Halske themselves are circulating a warning against low-watt lamps, and state that 16-c.p. lamps which require 1½ watts per candle at the beginning give only 4½ candles at the end of 55 hours, the number of watts per candle thus increasing from 1½ watts to 4½ watts.

There are central-station projects afoot at various places. First of all, the municipality of Frankfort is preparing, still preparing to make up its mind. Dresden is also trying to discover the ideally-best project for lighting the town. At Aix-la-Chapelle Schuckert and Co. have commenced building a station. At Bremen the same firm has just begun excavating the 45 kilometres of trench, into which they will place 180 kilometres of cable. At Limburg on the Lahn W. Lahmeyer and Co. of Frankfort will utilise water-power for lighting the town, which is 2 kilometres distant from the source of power.

CORRESPONDENCE.

THE DIMENSIONS OF PHYSICAL QUANTITIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In answer to my question, "W. M. M." seeks to establish a distinction between the numerical identity given in my last letter and the symbolic expression $t\,[T] = l\,[L]$, in which, according tohim, all the four symbols represent abstract quantities. The distinction is only that between a special case and a generalised expression, and there is not the least difficulty in employing the latter if it is preferred.

Thus, if a, b, x, and y, are all abstract quantities the two sides of the equation $ax = by$, can be compared. If we write $a = t$, $x = [T]$, $b = l$ $y = [L]$ (which is legitimate if [T] and [L] are abstract), we get the equation $t\,[T] = l\,[L]$, the two sides of which cannot, according to Fourier's rule, be compared. At what point does the absurdity come in?

But whatever "W. M. M.'s" way out of the difficulty may be, it must be remembered that the meaning of a symbol as used by any writer is that which he assigns to it by definition. It is beyond dispute that competent authorities have used the symbols [L], [M], [T] to indicate concrete quantities. Maxwell, for instance, states that "if we write [L] for the unit of length, that is to say, the actual concrete centimetre or foot, and if x denotes the numerical value of a certain line, then the complete expression for the line is x[L]" ("Encycl. Brit.," Ed. IX., Art. Dimensions). He also distinctly contemplates the introduction of these concrete quantities into equations, stating that "we may regard the symbols which occur in the equations as themselves denoting lines, masses, times, &c., or we may consider each symbol as denoting only the numerical value of the corresponding quantity, the concrete unit to which it is referred being tacitly understood;" and he then proceeds to point out the

Yours very truly
Rayleigh

Digitized by Google

Digitized by Google

advantages of indicating separately the concrete unit and the abstract multiplier (*loc. cit.*).

On this point, then, there is really no room for useful controversy. The symbols, [L], [M], [T], as used by Mr. Williams, do by definition represent concrete quantities wherever they occur. The point to be discussed is whether on the basis of this definition a scheme of dimensions can be elaborated for complex physical quantities by which the nature of each shall be conventionally indicated as surely as "an actual concrete centimetre or foot," or other unit of length is conventionally indicated by [L].

Even if this be granted there is still room for difference of opinion as to the dimensions of quantities with the physical nature of which we are imperfectly acquainted.—Yours, &c.,

ARTHUR W. RÜCKER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The assertion that x and y are *independent* variables, and that at the same time $ax = by$ is a contradiction in terms—that is where "the absurdity comes in."

I willingly concede to any writer the liberty to define his terms; my complaint was of a lack of definition. Anyone has a right to use L to denote a foot or a centimetre; but if he afterwards uses the symbol L^3 we are entitled to call upon him to explain what he means by the square root of a volume. If he uses the symbol LT^{-2} we may ask him to define the ratio of concretes of different kinds, and to explain what "the square of a time" may be.

An encyclopædist should not pose as a partisan, and since there are, unhappily, "two methods of interpreting the equations relating to geometry and other concrete sciences," Maxwell was bound to say so, and accordingly he states them both fairly in the words quoted by Prof. Rücker. But as to his preference he leaves no doubt. "If we adopt the first method we shall often have a difficulty in interpreting terms which make their appearance during the calculation. *We shall therefore consider all the written symbols as mere numerical quantities,** and therefore subject to all the operations of arithmetic during the process of calculation. But in the original equations and in the final equations, in which every term has to be interpreted in a physical sense, we must convert every numerical expression into a concrete quantity by multiplying it by the unit of that kind of quantity." The last sentence seems at first sight to sanction the multiplication of concretes; but it is, at least, open to the interpretation that our equations are formed from relations between concretes, and that the final result must be interpreted as a relation between concretes. That such a relation may take the form of an equation no one would deny; thus 3 feet = 1 yard is a physical equation which is perfectly intelligible; and so the expression x [L], as the complete expression for a length, where [L] is the concrete unit, is intelligible; but, in general, if such expressions are introduced into working equations "we shall have a difficulty in interpreting the terms which make their appearance." For this reason I decline to allow that the symbols [L], [M], [T] represent concrete quantities "*wherever they occur.*" The dimensional equations are obtained in one sense, interpreted in another, and half the scientific world falls a victim to the fallacy, *a dicto secundum quid ad dictum secundum alterum quid*; or, in the vulgar tongue, ringing the changes.

The truths of mathematics and mathematical physics have this peculiarity, that they command the assent of every sane man capable of understanding the processes by which they are obtained.

It follows that it is a grave objection to any such physical theory that a competent person who has examined the subject refuses his assent. Now no one can dispute either the sanity or the competence of the late Prof. James Thomson; yet in a Paper still unanswered, read before the British Association in 1878, he strongly affirmed the *change-ratio* view of the dimensional equations, and denounced, for reasons similar to those you have lately given me an opportunity of expressing, the, so-called, physical equations. "We have no right," he says, "to speak of dividing one quantity by another of a dissimilar kind, except, merely for brevity, in the case of dividing the numeric expressing the one quantity by the numeric expressing the other quantity, after we have fixed upon units of the two things."

I can understand Prof. Rücker's reluctance to accept the challenge to define his position, and his anxiety to escape the main question on the plea that there is "no room for useful controversy." But I cannot regard as useless a protest against a system which produces such a parody of scientific research as Mons. Vaschy's "Possibility of reciprocal action between an electrified body and a magnet."—Yours, &c.,

W. M. M.

TRADE NOTES AND NOTICES.

TENDERS INVITED.—The Vestry of St. Pancras invite tenders for various supplies, fixing, &c., required in connection with their extensive installation in the St. Pancras district. Further particulars are given in our advertising columns, and drawings and other documents can be seen at the offices of Prof. H. Robinson, C.E., 13, Victoria-street, S.W., where copies of the various specifications can also be seen. Tenders are to be sent to Mr. Albert E. Pycraft, at the Vestry Hall, Pancras-road, N.W., by Monday, the 22nd instant.

——— Offers are invited by the Corporation of Croydon for the transfer of the powers granted to the Council under the Croydon Corporation Electric Lighting Order, 1891. Tenders should be sent to Mr. C. M. Elborough, town clerk, by 11 a.m., on Thursday, September 15th. Further particulars will be found in our advertisement columns.

——— The Hartlepools Co-Operative Society invite tenders for lighting their new premises in Whitley-street, West Hartlepool, by electricity. Specifications (for which 2s. 6d. will be charged) may be obtained from Mr. T. Tweddell, 18, Read-street, West Hartlepool, to whom tenders must be delivered not later than Friday next, the 12th inst.

——— The Chertsey Union invite tenders for the construction of telephones, electric bells, and speaking-tube at the Union workhouse at Ottershaw, according to a specification to be seen at the office of Mr. H. E. Paine, clerk, Chertsey, to whom tenders must be sent on or before Monday next, the 8th inst.

TENDER ACCEPTED.—At a recent committee meeting of the Gas Commission it was decided to accept an offer from Messrs. J. and H. Whyte and Cooper, Britannia Engine and Boiler Works Dundee, to supply and erect for the electric lighting station (1) three steel boilers, with mountings, £1,260; (2) brick work, £190; and (3) air condensers, &c., £1,225—a total of £2,675.

APPOINTMENT VACANT.—A clerk of the works is required by the Bristol Urban Sanitary Authority to superintend the erection of the buildings, machinery, and distributing plant in connection with their electric light station. Applications must reach the Town Clerk before the 25th inst.

AWARD.—A prize medal has been awarded to Mr. John Spencer, of Wednesbury, for his exhibit of iron tubes and fittings for electric lighting purposes, &c., at the recent Crystal Palace Exhibition.

CAMBERWELL.—The Vestry of Camberwell having unanimously decided in favour of the introduction of an electric lighting plant on the site of the extensive new Public Baths and Washhouses at Camberwell Green, the Commissioners have at once put this work in hand and appointed Mr. Morgan Williams as Consulting Engineer. The contract has been secured by Messrs. B. Verity and Sons.

LEWES.—The Corporation have appointed a sub-committee to confer with a sub-committee of the County Council as to the lighting jointly by electricity of the County Hall and the municipal buildings.

LLANELLY.—At a meeting of the Local Board on Friday, it was reported that Mr. J. C. Howell had withdrawn his offer with reference to the electric lighting of the district, and decided not to accept the offer of Messrs. Andrews. The clerk was instructed to communicate with the Board of Trade upon the subject of the Provisional Order and the position of the Board thereunder, and upon receiving their reply the question will be further considered and a report made to the Board.

MITCHELSTOWN.—Mr. Abraham Sutton, of Cork, proposes to introduce the electric light in this town, and his proposal is receiving general support.

NELSON.—The Local Government Board have sanctioned the borrowing by the Corporation of £4,000, to carry out the first portion of the electric lighting scheme prepared by the gas manager.

Digitized by Google

ATELIERS HOSTER DE SAINT-NICOLAS (LIMITED).—A petition for the compulsory winding-up of this Company was presented on the 27th ult., and will come before Mr. Justice Vaughan Williams on the 9th inst.

BANKRUPT.—Rankin Kennedy, electrical engineer, Carntyne Electric Works, Glasgow, was adjudicated a bankrupt on the 26th ult. Creditors (amongst whom are the following) are to meet in the Faculty Hall, Glasgow, on Tuesday next, the 9th inst., at 12 o'clock :—

Dorman and Smith	£9	18	4
Electrical Power Storage Company (Limited), London	4	2	0
Electrical Review, London	8	15	9
Glover (W. T.) and Co., Salford	44	5	4
India-Rubber, Gutta-Percha, and Telegraph Works Company (Limited), London	4	16	9
London Electric Wire Company (Limited), London	2	14	11
McLean (Andrew) and Co., Bridgeton	87	7	0
McLellan, P. and W. (Limited), Glasgow	10	15	9
Paterson and Cooper	10	10	6
Reid (Matthew) and Co., Glasgow	8	0	1
Richard Frères, London	3	4	8
Rome, James, Glasgow	69	6	2
Sankey (Joseph) and Sons, London	62	0	4
Thomson (W. R. M.) and Co., Glasgow	60	0	0
White, James, Glasgow	13	6	0
Yuille (Robert) and Sons, Glasgow	39	17	10

The total liabilities are set down at £714. 14*s*. 9d., and the assets, after deducting preferred claims, at £2,055. 2*s*. 5d.

COLCHESTER.—At a meeting on Wednesday the Town Council decided to take steps to obtain a Provisional Order for lighting the town by electricity.

The Crystal Palace Company and the Electrical Exhibition.

The ordinary general meeting of the shareholders of the Crystal Palace Company was held yesterday (Thursday) at the Cannon-street Hotel, under the presidency of Mr. G. T. Rait. In the course of his remarks in moving the adoption of the report, which was agreed to, the Chairman stated that the receipts from admissions during the half year ended June last had been £6,400 in excess of those of the corresponding period of 1891. This, he need hardly tell them, was due to the Electrical Exhibition ; but they must not congratulate themselves on the receipts before looking at the expenditure. The decrease in their receipts of £1,000 on account of reserved seats was no doubt due, to a certain extent, to the Electrical Exhibition attracting people from the other amusements. In the item of special *fêtes* there had been a decrease in the expenses of £3,000. They had to expend an enormous sum under this heading to attract the public, and the reason for this decrease of £3,000 was simply that the Electrical Exhibition had caused an expenditure of £7,344, which was £4,000 more, after allowing for the decrease of £3,000. This was an enormous expenditure, no doubt, on the Electrical Exhibition, and he must confess that they had been somewhat disappointed with the financial result. The large expenditure mentioned was due to the fact that in the present case the Company had had to provide the motive power to a certain extent, whereas in the case of the Exhibition of 1882, the exhibitors themselves provided this power. Fire insurance during the half-year had cost the Company £2,000, or an increase of £1,200, which was also a very heavy tax upon them in connection with the Exhibition. At a previous meeting he told them that the Directors hoped that the fire insurance people would make some reduction in the extra premium and generally in the amount for insuring the Palace. Immediately after the meeting Mr. Gardiner and himself had an interview with the fire insurance committee, when they went thoroughly into the question, the result being, he was happy to say, that the Company were met to some extent. The Committee wrote to them to the effect that if they would adopt the electric light in their theatre (this seemed a singular request in face of their having charged an extra premium for the Electrical Exhibition), and make their sprinklers automatic, they would reduce the premium from £1. 11s. 6d. per cent. to £1. 5s. per cent., and would also reduce the amount which it was arbitrary upon them to insure for from £100,000 to £80,000. He thought they could manage this, and he hoped that they would do so before long. They had the matter now practically under their consideration. It would, perhaps, be wiser for them to do this than to adopt an insurance fund of their own. He must say that he had to some extent dreaded the responsibility of having their huge property uninsured, but he thought that if they were insured for £80,000 at 25s. per cent. premium—subject to certain rebates for commissions—they would be doing a good thing, and there would be a material reduction under this head. They had not abandoned the hope of getting back the £700 or £800 extra premium from the insurance offices. They did not ask for the money back, but what they said was this : If we have no claim upon you for a serious amount during 1893, will you credit us with that amount on our premium ? That was all that the Company asked for, and he thought that this request ought to be complied with. They took every possible precaution to guard against fire ; and the fact that they had not had a single outbreak was a great proof of the advantages of electricity from a fire insurance point of view, and he was very pleased that the insurance offices had themselves suggested the adoption of the electric light in the theatre at the Palace.

COMPANIES' MEETINGS & REPORTS.

Anglo-American Telegraph Company (Limited).

The ordinary general half-yearly meeting of the proprietors of the Anglo-American Telegraph Company (Limited) was held at Winchester House, 50, Old Broad-street, on Friday, the 29th ult., under the presidency of the Most Hon. the Marquis of Tweeddale.

The SECRETARY (Mr. T. H. Wells) read the notice convening the meeting and the minutes of the last meeting, the latter being confirmed and signed. The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN then said : The report contains two announcements, both of a very melancholy nature. I refer, in the first place to the death of our much esteemed and distinguished colleague, Mr. Cyrus Field. Mr. Field was a man of great ability and tenacity of purpose, and having early convinced himself of the feasibility of connecting England with America by means of a submarine telegraph cable, he applied himself with astonishing energy and perseverance to the accomplishment of this important object. After surmounting many difficulties, and after repeated disappointments, his efforts were finally crowned with success in the year 1866, since which time telegraphic communication with America has never been interrupted. Those who knew Mr. Field best, and were most closely associated with him in the great work with which his name will be always connected, are the first to bear witness to the value of his services, and to award him the honourable title of Pioneer of Atlantic Telegraphy. (Applause.) Mr. Field at all times took an active interest in the affairs of our Company, of which he was an original director. You join us, I know, in an expression of sincere regret at the loss we have sustained through his death. The second incident to which I have referred is the terrible calamity which has befallen the town of St. John's. Our connection with the Colony of Newfoundland dates from the year when the exclusive right of landing submarine telegraph cables was secured to the Company mainly through the exertions of Mr. Field. We own land lines and telegraph and telephone stations in St. John's, and have not escaped serious injury. But this is a small matter compared with the widespread ruin to the inhabitants caused by the fire ; and I am sure the shareholders of this Company will heartily endorse the action of the Directors in contributing to the relief of the sufferers. Turning now to the operations of the half-year under review, it is a source of satisfaction to be able to point to a steady, if slight improvement in our traffic receipts, amounting for our share to £10,000. Unluckily, our expenses have increased as well, so that comparatively a small portion of the increase is available for dividend. The expenses of the s.s. "Minia" are higher by £3,000, mainly in consequence of repairs required by the Board of Trade. Working expenses are about £2,000 in excess of the preceding half-year, the increase being almost exclusively due to the expenditure on new stations rendered necessary by the keen competition for business. Then we are minus the £1,500 which the s.s. "Minia" earned for us in 1891. The net result is a sum of only £3,500 over and above the corresponding half-year of 1891, applicable to dividend, or just sufficient to pay an additional 1s. per cent. on the half-year. Having regard to the extraordinary stagnation which has prevailed in commercial circles ever since the Baring failure, as well as to the active competition for Atlantic telegraph business, to which I have just referred, the result cannot be regarded as altogether disappointing. Speaking for myself, I cannot but believe that the day will come when the rival Companies will see the advantage of making some arrangement by which the enormous amount now unprofitably spent—I might say squandered—in competition would be saved and the public in no way prejudiced, but, on the contrary, greatly benefited. Certain it is that until something of the kind comes to pass, we cannot hope for any diminution in our working expenses. The state of the renewal fund is naturally an object of great interest to all classes of shareholders, and it will no doubt be a great disappointment to find that, owing to the large expense attending the repairs of cables, more particularly the Brest Cable, the time has not yet arrived when we could consider the propriety of applying the interest to dividend. It is this which renders another break in the same cable, mentioned in the report, all the more tantalising, for its repair must entail a considerable expenditure. The repairing ship is on the spot, and if the weather continues fine we may hear any day or even hour of the repair having been effected. With regard to the lawsuit I have nothing to add to what is stated in the report. I met our French solicitor in Paris a short time ago, and learned that there was little prospect of the appeal being reached before the spring of next year. Our duty is clear, and it is to maintain the high state of efficiency for which our service is distinguished, and we trust to that to receive a still larger share in the public business. In conclusion I have only to express the opinion that, although the increase in our expenses is a regrettable feature, yet being more than balanced by increased traffic receipts—an increase which has occurred in a time of unexampled commercial depression—we are entitled to look forward with confidence to a more prosperous state of things in the coming half-year. With these remarks I beg to move—

"*That the report of the Directors and the accompanying statement of accounts to the 30th June, 1892, submitted to this meeting be and the same are hereby received and adopted.*"

The DEPUTY-CHAIRMAN (Mr. Francis A. Bevan) seconded the motion.

Mr. GRIFFITH said the shareholders would no doubt all join in the expression of regret at the death of Mr. Field. They could only hope that his mantle had fallen upon persons able to carry on the great work which he initiated, and he thought that they had reason to say that that hope

Digitized by Google

was to a great extent already justified. Notwithstanding the luminous statement given by the Chairman, there were many questions that struck him as worthy of consideration, and one was that they might improve the balance-sheet if they could get rid of the very large item, "unclaimed dividends." As they at present stood, perhaps they could not do so; but it seemed to him that the time was rapidly coming when they might consider whether that amount should not be distributed among the deferred shareholders, who had for so long a period received no dividend at all. Of course in these transactions they must act according to strict rule, and that he hoped they would always do. What he desired was that the Directors would accelerate the time when the deferred shareholders would get some relief.

Mr. E. H. BOURNE suggested whether it would not be wiser to let the Brest and St. Pierre cables lie and rot at the bottom of the sea, seeing that it cost £20,000 to £25,000 a year to repair—a sum equal to one per cent. dividend.

The SECRETARY: £25,000 would represent only ⅝ per cent.

Mr. BOURNE said he knew that all the repairs which had been done to the cable were of no practical use. As soon as it was repaired it was broken again—in a month or so; and under the circumstances would it not be better to abandon it altogether?

Mr. HANCOCK said that the position of the deferred shareholders had been referred to at these meetings from time to time. There was a deferred capital of over £2,900,000 upon which nothing had been paid for a long time, which was not a creditable thing to the Directors of the Company. He thought that the time had come when the Board ought to turn their attention to such a remodelling of the state of affairs by which the deferred shareholders would receive something for their money. He thought that it was their duty before the next meeting to give serious consideration to the matter and propose a scheme which would be more just to that class of shareholders.

Mr. LOTT noticed that there was generally a good deal of grumbling at these meetings from the deferred shareholders. There were two methods by which they might help themselves; let them sell deferred and buy preferred shares. He had done so himself. The other was to help the Company to prosper by all the means in their power. He was interested in several companies which traded with America, and he had always endeavoured to induce the people who were in the habit of sending cablegrams across the Atlantic to do so through the Anglo-American Company. He really could not see that there was any ground for grumbling at the management of the Company, for he thought it was a most eloquent testimony to their ability.

The CHAIRMAN said that he was afraid he could not help Mr. Griffith in the matter of the unclaimed dividends. He did not understand whether that gentleman suggested that they should make use of that money now.

Mr. GRIFFITH was understood to suggest that after a reasonable time in the future the money should be forfeited for the benefit of the deferred shareholders.

Mr. CHARLES BURT: The Stock Exchange will not allow a quotation of the shares of a company which has that clause in its articles.

The CHAIRMAN said that the Brest Cable was a most disappointing one, owing to the cost of the repeated faults in it. If they could place it in some safe part of the ocean they might probably be relieved from these accidents, but this could not be done without a large expenditure. But they could not get on without it. They could not do without their communication with France, for in that case they would lose the traffic. Mr. Hancock had suggested the remodelling of their affairs with the view of giving the deferred stockholders a dividend. But he (the Chairman) honestly did not think that their affairs could be so remodelled. The dividends were declared on the ordinary stock, and the deferred could only get something after the preferred had received its full dividend. As to the reserve fund, that was another matter; if the whole of the interest of the reserve fund had been placed to dividend account it would not have benefited the deferred shareholders at all; and they did not propose to take any of the reserve fund until it reached £1,000,000. He hoped that the favourable remarks made by Mr. Lott would be shared by the other stockholders.

Mr. GRIFFITH proposed and Mr. NEWTON seconded a vote of thanks to the Chairman, which was carried unanimously.

The proceedings then terminated.

Direct United States Cable Company (Limited).

The thirtieth ordinary general meeting of this Company was held on the 29th ult., at Winchester House, under the presidency of Sir John Pender, K.C.M.G., M.P. (Chairman of the Company).

The Secretary (Mr. T. Finnis) read the notice convening the meeting, and the minutes of the last half-yearly meeting, which were confirmed.

The CHAIRMAN then said: Gentlemen, I presume you will take the report as read. Before moving its adoption I shall, as usual, go over some of the figures which refer to the last six months' operations, so that you may carry away with you a perfect idea of the working of this business. The revenue for the half-year to June 30th last., after deducting outpayments, amounted to £39,015, and the working and other expenses, including income-tax and depreciation of spare cable, but exclusive of cost of repairs, to £19,019, leaving a balance of £19,996 as the net profit of the half-year, making, with £4,983 brought forward from the previous half-year, a total of £24,979, which has been appropriated as follows:—Interim dividend of 3s. 6d. per share for the quarter to March 31st, £10,624; proposed final dividend of 3s. 6d. per share for the quarter to June 30th, £10,624; balance proposed to be carried forward, £3,731; total, £24,979. The revenue, as compared with that in the corresponding period of last year shows an increase of £1,662. This is not a large improvement, but business generally has not been brisk during the period under review. The expenses in London show a small reduction in salaries and a small increase in printing and stationery, the other items being practically the same as before. These disbursements are, on the whole, £24 less than in the corresponding period. The expenses at stations also show a small reduction in salaries, and a considerable reduction in maintenance. On the other hand, rent and taxes are somewhat higher. The stations expenses on the whole have absorbed about £140 more than in the corresponding period. The further general expenses show a reduction in Directors' remuneration and a small increase in law charges; but taking the normal working expenses as a whole, it will be seen that they are only £49 in excess of those in the corresponding period, viz.:—£17,604, against £17,555. The remaining items charged against revenue are income tax, depreciation of spare cable, and freight of cable. These are items which are scarcely under control, and it is to these items alone that the increase shown in the expenditure, as a whole, is due. Turning now to the reserve fund account, it will be seen on the credit side that the interest on the investments amounted to £4,421, while on the other side the amount charged for repairs of cables is £9,385, leaving the balance of the reserve account standing at £254,716. In the balance sheet a sum of £9,000 is standing on the "acquisition of patent rights account," and represents the balance of amount paid on that account in lieu of continuing an annual payment of royalty, and covers also any and every improvement made since the date of the Company's original duplex agreement. It is proposed to write off this balance against the revenue account at the rate of £2,000 per annum, which is exactly the sum heretofore charged to that account for the duplex royalty. It will be in your recollection that this duplex system, which is probably one of the most remarkable inventions since submarine telegraphy has been established, has practically doubled the working power of our cables. I have always considered that but for that system we should have probably required more cables; but with the existing cables together with the duplex system, we have a great deal more carrying power than the present traffic requires. The investments remain unaltered since the last meeting, and their present market value continues much higher than the figure of "cost" at which they stand in the accounts. This completes a brief summary of the accounts for the half-year; but it must be borne in mind that the June six months is always the lean period, and no fair idea of the working can be obtained without looking at the twelve months as a whole, and when so considered it will be seen that the Company, after paying all expenses, including somewhat heavier repairs than usual, together with the usual dividend of 3½ per cent., has fully maintained its position during the past financial year. Now, gentlemen, I have given you what you would call the hard facts connected with the working of our system. I should only have been too pleased to have told you that our dividend-earning power is increasing, but unfortunately the amount of cable power in the Atlantic, allowing for the duplex system, is equal to something like twenty cables. I remember in the early days of submarine telegraphy the difficulties we had to get sufficient money to lay one cable. But the first cable was laid after great difficulties, and it was duplicated. Then America began to take heart and laid cables, with the result that we are labouring now under what I may call a surfeit of cables in the Atlantic. I hope that those who look to this field for a harvest in the future will take to heart the lesson taught by the fact that at the present time we have sown a great deal more than we are yet reaping a return from. Having said so much upon the working of the system, there are two or three other things I should like to refer to. In the first place since I met you six months ago we have had some great changes. Old friends have passed away—friends who were associated with submarine telegraphy from its inception. Foremost amongst these is Cyrus Field, who was particularly active and prominent in the earlier history of submarine telegraphy, especially Atlantic telegraphy. I recollect shaking him by the hand when he first came over to this country, and I was one of the first men who joined him in his Atlantic cable enterprise. Cyrus Field was a man of indomitable energy; but somehow or other a series of difficulties occurred in those earlier days, and for a few years Field's activity in America did not result in inducing the public to subscribe the necessary money to go forward with. The movement, however, was taken up on this side, and owing to the courage and perseverance characteristic of the people of this country we were enabled to go on and obtain success. Knowing Cyrus Field as I did I say we are deeply indebted to him for the active and energetic part he took in those earlier days; and when the history of submarine telegraphy is recorded his position will not be a mean one in that record. And then, gentlemen, since I last addressed you, we have lost two Directors. Mr. Ford, as you know, had to do with this Company since it became what I call a rescued Company—a Company that had for years existed but which paid no dividends—and had continued to be associated with it from the time when we entered upon a new departure, and paid fair dividends. The other Director whom we have lost is Admiral Mayne, M.P., who was also connected with us from the beginning. They have now passed away. Both were valuable and experienced men, and I have here, as one of their colleagues, to express deep regret at losing them. But such is life. These changes will occur, and the result is that other men take their place and the world goes on very much as before. There is another question, and that is the French suit. We have not mentioned it in the report because we are so tired of seeing it there from time to time without being able to give any definite information, and we thought it better to leave it out. All I can say is, if you ever quarrel with a Frenchman, never get into a lawsuit with him. I frankly tell you that I do not see the end of the case any more than I did at the commencement. I do not suppose it is a very expensive business, because surely even lawyers cannot run up bills without working, but we have a suit which seems to me to be interminable. We think we are in the right. I might mention that this suit is managed from this side by our colleagues, the Anglo-American Company, but I must leave it to wiser heads than mine to

Digitized by Google

say when it will be decided. At all events we shall keep a watch upon it, and I shall be immensely pleased if it terminate in my day. We have had, gentlemen, more than the ordinary amount of expenditure upon repairs during the past six months, but we have made it a rule that as soon as a break occurs to take steps to repair it. That course we have always pursued, and, unfortunately, the necessity arises a little oftener than is pleasant for us, and satisfactory for the exchequer. And then we cannot stand still. Our people have been living in wooden huts at Ballinskelligs, and we now find it is necessary to spend a little money there. The expenditure will be made judiciously, and it will not affect your dividends. At any rate, our people will be housed more comfortably, which is a matter that must always receive proper consideration. We are trying to maintain our fair share of the working in the pool, and we are spending a little more money on canvassing, and so far as we have gone the result of the canvass has been to pay us fairly well for the sum of money expended upon it. Now, gentlemen, as I have often said here, submarine telegraphy is a great barometer of trade. What is going on here in England is known at once all over the world, and what is going on all over the world is at once known in England. And trade is affected for good or bad according to the state of the political horizon. I hope there is good trade still in store for us, but I also say that until we are settled down upon a firm sound basis, trade will not grow. Trade rests upon confidence, and when confidence is assured—as I hope it will be in this great and grand old country—you may depend that after a cycle of depression we shall have a cycle of prosperity, and in that prosperity the submarine telegraph system will always largely share. I beg now to move :—

"*That the report of the Directors, dated July 15th, 1892, together with the statement of accounts to June 30th, 1892, annexed thereto, be and the same are hereby received and adopted; and that a final dividend be now declared of 3s. 6d. per share, free of income tax, making, with the interim dividends already paid, a total dividend of 3½ per cent. for the year ended June 30th, 1892.*"

Mr. E. M. UNDERDOWN, Q.C., seconded the motion.

Mr. JOHN NEWTON regretted, as he had wanted to attend the meeting of the Anglo-American Company, that the meetings of the two Companies had been convened, for the first time, on the same day and at the same hour. Many other shareholders besides himself would have liked to have been present at both meetings.

The CHAIRMAN said he believed he was personally to blame. It was not an accident, but it arose from circumstances which were difficult to control. They had always tried to have a week between the meetings of the two Companies, but it so happened that the election business came up this time, and he could not be in two places at once. At one time they had thought it might be possible to have held the meeting last Friday, but a good deal of work crowded into that day, and they therefore resolved to hold it to-day.

Mr. NEWTON said that the difficulty would have been overcome if the Direct Meeting had been called for one o'clock instead of two. Everything else was, however, satisfactory, including the dividend. He felt sure that the death of a man like Mr. Ford was a cause of grief to all the proprietors. The death of Mr. Field was a great loss to the enterprise of telegraphy; and there was one feature in connection with his death which he (the speaker) could not help being struck with. He referred to the acknowledgment in the Press of Mr. Field's services, and the very little acknowledgment, if any, which was paid to those who provided to a large extent the funds for the grandest work ever accomplished.

Mr. MARMONT asked if there was any idea of issuing the 4,000 unissued shares, and if so, whether they would be issued *pro rata* to the shareholders.

The CHAIRMAN replied that the fact was that they did not want the money, and they did not wish to increase the capital. He therefore thought that it would be better to keep the shares where they were. They could not issue them at £20 a share, the par value, and they were not allowed to issue them under that.

The resolution was then unanimously adopted.

On the motion of the Chairman, seconded by Mr. James Pender, Mr. C. J. Günther was re-elected to his seat at the Board, as was also Admiral of the Fleet the Hon. Sir Henry Keppel, G.C.B., D.C.L., on the motion of the Chairman, seconded by Mr. Underdown.

Messrs. John G. Griffiths, F.C.A., and Mr. John Sawyer, F.C.A., were afterwards re-elected auditors for the ensuing year.

Mr. UNDERDOWN said it was unusual for a vote of thanks to the Chairman to come from the Directors' side of the table, but he thought the meeting would join with him in congratulating Sir John Pender upon his election to the House of Commons, and he had no doubt that the House would derive great advantage from the presence of their Chairman. He was fully convinced that Sir John Pender was one of the men who ought to be in the House, and who ought to remain there.

The motion was adopted.

The CHAIRMAN : I am very much obliged to Mr. Underdown for the handsome way in which he has referred to me. I have been associated with this Company for a very long period. I believe that the submarine system, in which we all take such an interest, has done an immense deal during the last twenty-five years to promote not only the commercial growth of the country—I may say of the world—but I think it has knit together the world in a way that makes us much more powerful than we were before submarine telegraphy was established. Some of you may think that in going into political life again at my age, I am doing a foolish thing, particularly after I have had all the comforts and enjoyments of six years out of it. But there are times in the history of the country when the oldest and the youngest men ought to feel that they have a duty to perform. I look upon the present period as one marking a crisis in this country, and I feel that with the life I have led heretofore, and with the little life I may have still left in me, I should not like to be out of the fray in maintaining the integrity of the country of which we are all so proud, and which many of us have taken an active part in building up. There is nothing political, I hope, in this ; it is simply patriotic, and nothing more nor less.

The proceedings then terminated.

Crompton and Co. (Limited).

The fourth annual general meeting of the members of Crompton and Co, (Limited) was held at the City Terminus Hotel, Cannon-street, on Friday. July 29th, to receive and consider the report of the Directors, and the audited statement of accounts and balance sheet for the year ending March 31st, 1892, to elect a Director and auditors, and to transact the ordinary general business of the Company. Mr. Rookes Evelyn Bell Crompton (one of the Managing Directors) presided.

Mr. Francis R Reeves (the Secretary) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN : Gentlemen,—I have now to move that the Directors' report and statement of accounts for the year ending March 29, 1892, be taken as read and received, and adopted. I am happy to say that the remarks that I have to add to-day on the subject of the report will be brief. Happy is that Company which has got nothing to explain away ; and that is our case. We have carried on the year's business in a manner which has been substantially satisfactory. The reason that our profits have not been still larger is due to no want of economy in our working ; for I may say that by watching and diligence we are now working at a greater economy than we have ever reached before. But it is simply due to the fact that there has been greater competition, and consequently prices have been reduced, and the margin available for profit upon the various orders has been very much smaller than formerly. Our electrical business, as you know, is a very progressive one, it demands great sacrifices on the part of manufacturers, and, which is a matter of very great importance, the sums are practically taken away from the profits of the year—the sums which have been devoted to improvements, as it is quite impossible to sub-divide up all these items so as to put them to a suspense account. The nature of the work which has been carried on during the year has been, some of it, of a special character, and we have taken our share of the contracts which have been going. We have done a certain amount of these large contracts, and our name has been published in connection with such as the Notting-hill, the Westminster, and other London contracts. We have also completed our contract for the lighting of the City of Pretoria in the South African Republic. At the present moment we are in negotiation for some very large contracts of a most important kind, but which for obvious reasons I do not specify more particularly here. Perhaps, however, I might say that your Directors believe that our prospects of profit in connection with all of these contracts—if they are obtained by us—will be at least as good as the results have been from those that we have undertaken in the past. And as our economy in working has been exceedingly progressive, I hope if we do obtain these contracts that we shall be able to show you at least as good profit as we have made in the past—if not a greater one. The experiments, or rather the money that we have spent in experiments, in connection with electrical hauling, has been so far completely successful, and we are receiving orders for electrical hauling plant to an extent that already occupies a very considerable proportion of our order sheet. The next point that I must notice is that we have no trouble whatever with our workmen. Our workmen, we find, are very steady going, and there is a state of good feeling grown up between our workmen and ourselves which is very gratifying, and which still continues. We have been trying an experiment during the past year of a very interesting nature—it has been this, that we have issued a certain number of our debentures to our workmen, under such terms that although the workmen have the perfect security which our debentures afford, they are allowed to participate in the profits of the undertaking by having the interest that they receive on their debentures raised to a rate of interest equal to that which is paid on the ordinary shares. That, gentlemen, virtually makes our workmen partners with ourselves in the undertaking, and I hope that the plan will have a very good effect in the future. The scheme has been at work for such a very short time that it is quite impossible to be able to tell at present as to what its effect has been. But the fact that those who have taken these debentures, men such as our foremen, chief managing clerks, and other men who can materially assist us in making our profits, is a fact that, taken by itself, is a very encouraging sign. I have another word to say. You are aware that we have not for some time past had a regular chairman; but I am very glad to tell you that one of our Directors, Viscount Emlyn, whom we have had for some time upon our Board, now finds his engagements such that in the course of the next few months he hopes to be able to take upon himself the position of permanent chairmanship of this Company, and I need hardly say that this will be a very great relief to me personally, my own work as Managing Director being sufficiently engrossing and taking up so much of my time that it is quite impossible that I could do justice to the two offices; and I think it will be a very great advantage to us to have such a well-known and well-tried business expert as Viscount Emlyn to occupy the position of Chairman of this Company. I do not know that I have much more to tell you. You may, perhaps, remember that I stated to you last year that we propose to issue the balance of the preference shares, and that it would be a great advantage to the existing shareholders that that balance should be so issued, as it would enable us to obtain a Stock Exchange quotation on these new shares, and the same remark applies to the small balance of debentures that yet remain unissued. So soon as those two balances are issued, we

Digitized by Google

shall be in a position to apply to the Stock Exchange for a quotation for the new issue of the preference shares and for our debentures also; and I have no doubt that you will consider that will be an advantage I feel certain that you will agree with me that taking into consideration the reduction of prices, due to competition, and the fact that trade, as a whole, has been rather on the decline, during the latter half of this year, that the profits earned are very satisfactory, and that they really require no further comment on my part. These profits have been earned by keeping down expenses and careful management, and I think that we have very greatly to thank our administrative staff for the excellent results obtained. I conclude by moving—

"That the Directors' report and statement of accounts for the year ended March 31st, 1892, be received and adopted."

Viscount EMLYN seconded the motion.

The CHAIRMAN invited discussion.

Mr. T. R. TUFNELL: Well, Mr. Chairman, I need hardly say that I do not rise to propose an amendment to the report. I agree with you, Mr. Chairman, in looking upon it as one of a most satisfactory character, but there is one suggestion I should like to make, and it is this: Looking at the steady progress which the Company appears to be making, and the profitable business which the Company appears to be doing, and the admirable way in which our business appears to be conducted in every respect, and also to the increase which has lately taken place in the number of our Directors, and certainly considering that which you have just mentioned, the addition to your numbers of Viscount Emlyn—who I shall be only too pleased to see the Chairman of the Company—under these circumstances I should like to suggest that some sum beyond £1,000—say, £1,300—should be paid to the Directors annually as their remuneration—that is, that they should get an addition of £300 per annum—if any gentleman on this side of the table will second my proposal.

Mr. HANCOCK: I shall be very pleased to second that.

Mr. TUFNELL: Perhaps, Mr. Chairman, you could hardly put that resolution; it would come from the shareholders.

The CHAIRMAN: Yes, sir, from the shareholders; but I think, perhaps, it would be more convenient if you would permit the resolution which you have just raised to stand over for little while, and that I should now, subject, of course, to any questions any shareholder may desire to ask thereon, put to the meeting the motion which has been moved by myself, and seconded by Viscount Emlyn, that the Directors' report and statement of accounts be received and adopted. Those who are in favour, on the contrary—that is carried. I have now to move—

"That a dividend of 3s. 6d. per share, being at the rate of 7 per cent. per annum for the half-year ending March 31st last, be declared and paid upon the preference shares of the Company."

Mr. B. GIBSON: I have much pleasure in seconding that.

The motion was carried.

The CHAIRMAN: I have now to move—

"That a dividend of 4s. 6d. per share, making with the interim dividend 7 per cent. per annum, be declared and paid upon the ordinary shares of the Company."

Mr. H. H. J. W. DRUMMOND seconded the motion.

The motion was carried.

The CHAIRMAN: I have now to move—

"That Mr. Carlton Fowell Tufnell be, and he is hereby, re-elected a Director of this Company."

Mr. Tufnell has been a Director of this Company from the first, and is one of the hardest of our workers. It is not necessary for me to say anything further beyond that I sincerely trust that he may be re-elected a Director of this Company.

Mr. PAYNE: Would you like it seconded from this side of the table?

The CHAIRMAN: If you please.

Mr. PAYNE: I shall be pleased to second it.

The motion was carried.

The CHAIRMAN: I shall be very glad if some shareholder will move the re-election of the auditors.

Mr. PAYNE: Mr. Chairman, I had the privilege of proposing that resolution last year, and I have much pleasure in doing so again this year. The accounts appear to be thoroughly well kept, and it seems to me that Messrs. J. H. Duncan and Co. do their work as it ought to be done, therefore I have no hesitation in placing their names before the meeting—that they be re-elected as auditors for the ensuing year, at the usual remuneration of 25 guineas.

Mr. T. R. TUFNELL seconded the motion, which was carried.

The CHAIRMAN then intimated that they would be prepared to receive Mr. Tufnell's resolution.

Mr. T. R. TUFNELL: Mr. Chairman, as I am in order now, I shall be glad to move—

"That looking at the steady progress which the Company is making, and the increase which has taken place upon the Board of Directors, the Directors' remuneration be increased by the sum of £300 per annum."

Mr. HANCOCK seconded the motion.

The resolution was put and unanimously carried.

The CHAIRMAN: Gentlemen,—We have to thank you for your very kind vote, which I assure you will be greatly appreciated by the Directors. I have very little to add to what I have already said, that the Directors of this Board have had no easy task. Such a business as ours is one that entails a considerable amount of anxiety and of trouble upon the management, and I can assure you that we, the Managing Directors, have done all in our power to avoid any difficulty, and I do not disguise it that it is greatly due to the tact and management of the Board that we have succeeded, and I think, gentlemen, that you may felicitate yourselves upon having such a good Board. Unless any shareholder has any further questions to ask upon any subject, that concludes the business of the day.

Mr. T. R. TUFNELL: I do not know whether we may take it that the lesser is included in the greater; but, perhaps, you will permit me to propose a resolution, that the thanks—the cordial thanks—of this meeting be accorded to yourself as Chairman and to your co Directors, and I should like to include the name of our valuable Secretary, Mr. F. R. Reeves, and also our thanks to the staff.

Colonel WOOD seconded the motion, which was carried by acclamation.

The CHAIRMAN: We are much obliged to you, gentlemen.

The proceedings then terminated.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES DIRECTORY AND HANDBOOK, 1892, pages 308-322, *&c., &c.*]

BROADBOTTOM GAS COMPANY (LIMITED).—This Company was registered on July 28, 1892, with a capital of £1,400, in £1 shares, to acquire the retort-house, gas-holder, and other buildings at Broadbottom, in the county of Cheshire, and reserves the right to light the village of Broadbottom and the adjoining districts with electricity.

DAY'S GAS ENGINE COMPANY (LIMITED).—This Company was registered on July 29th, with a capital of £60,000, in £5 shares. The objects are to enter into and carry into effect an agreement, dated July 11, 1892 (the parties to which are not mentioned), for the acquisition of the English and foreign patents already or hereafter to be granted to Mr. Joseph Day, for improvements in gas-engines; to manufacture gas-engines under the said patents; to grant licences for the manufacture of gas-engines under the said patents; and to carry on the business of mechanical and general engineers, iron and brass founders, smiths, machinists, &c.

DOWIE AND HANDYSIDE (LIMITED).—This Company was registered on July 26th, with a capital of £4,000, in £1 shares, to acquire, and take over as a going concern the business of mechanical and electrical engineers, iron and brass founders, boiler makers, wire drawers, iron and steel cable makers, millwrights, metal workers, &c., carried on by Cecil M. Dowie and Charles B. Handyside, at 418, Oldham-road, Newton Heath, Manchester, under the style of "Dowie, Handyside and Co."

ONCKEN PATENT STAVELESS BARREL COMPANY (LIMITED).—This Company was registered on July 30th, with a capital, of £150,000, divided into 50,000 ordinary and 25,000 deferred shares of £2 each. The objects include the carrying on of the business of treating wood and other materials and substances by electricity and chemicals.

SLAG REDUCTION COMPANY (LIMITED).—This Company was registered on July 29th, with a capital of £50,000, in £10 shares, to enter into and carry into effect an agreement for the acquisition by the Company of certain patent and other rights for the use of attrition mills and magnetic separators, together with certain plant, machinery and premises, and to carry on the business of manufacturers of and dealers in machinery for crushing, grinding or separating materials or substances, smelters, engineers, iron founders, chemical manufacturers, &c.

SOCIETE D'ELECTRICITE DE LA MEDITERRANEE, SOUCHIER ET CIE.—A Company has been formed with the above title, with a capital of 250,000fr., to exploit the electrical industry in Marseilles and neighbourhood.

HOBART TRAMWAY COMPANY (LIMITED).—The statutory return of this Company made up to July 14th, was filed on the 26th. At the time of making up 45,067 of the total capital of £105,000, in £1 shares, had been taken up, of which 20,000 had been issued as fully paid. On the remaining 25,067 shares the full amount had been called, resulting in the payment of £25,061. 15s., and leaving five guineas in arrears. The total amount of shares for which share warrants, comprising five shares each, are outstanding, is £1,250.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended July 31st were £735, as against £692 for the corresponding period of last year, being an increase of £43. The total receipts for half-year amount to £3,784, against £3,477 in the corresponding period of 1891, being an increase of £307.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—At a meeting of the Directors of this Company, on Wednesday, audited accounts for the half-year to June 30th were submitted, and it was resolved, after providing for the dividend on the preference shares, to recommend a distribution on the ordinary at the rate of 8 per cent. per annum, free of income-tax. The estimated traffic receipts for the month of July were £3,100, as compared with £3,186 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The receipts of this Company for the month of July amounted to £1,684, as compared with £1,667 in the corresponding period of last year, an increase of £17.

Digitized by Google

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the month of July amounted to £49,117, against £52,303 in the corresponding period of 1891.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of July amounted to £41,714, and to £41,219 in the corresponding period of last year, an increase of £495.

KENSINGTON AND KNIGHTSBRIDGE ELECTRIC LIGHTING COMPANY (LIMITED).—An interim dividend has been declared on this Company's ordinary shares at the rate of 4 per cent. per annum for the half-year ended June 30, 1892.

NEW TELEPHONE COMPANY (LIMITED).—We learn that the subscription for shares in this Company, the prospectus of which appeared in our last issue, was largely over-subscribed, although the list was only open for a few hours. Over two millions is the figure given as the amount of applied for.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended July 29, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,028.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The receipts of this Company for the fortnight ended July 31, 1892, show a decrease of £57 as compared with the corresponding period of 1891.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 743.—Vol. XXIX. FRIDAY, AUGUST 12, 1892. PRICE SIXPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

The Edinburgh meeting of the British Association has been attended by a smaller number of members than was expected, though of course the attendance was better than last year. Every effort was made to encourage local interest by giving prominence to local notables. A good many men well known at scientific societies, but rarely seen at meetings of the British Association, had been attracted by the promise of an International Conference on Electrical Standards. In Section A, however, English spoken with a German accent was as noticeable as the more musical Scotch. The German contingent, led as it should be by Prof. von Helmholtz, added largely to the value of the proceedings; but, while most of their Papers and discussions were of great worth, they rather congested the programme, and thus upset the order and despatch of the work.

Out of 64 Papers read before Section A, there were 39 connected with, and for the most part entirely concerned with electrical science, and 25 were non-electrical. In Section G, out of 32 Papers, 10 were electrical and 22 were non-electrical.

The value of the extremely hurried work of Section A, as far as the Sectional Meetings are concerned, cannot be properly judged at present; and our readers, who will have an opportunity of seeing most of the Electrical Papers, or abstracts of them, in these columns, will be really in a better position to appreciate them than if they had heard them read. As to the Electrical Papers read in Section G, several, such as those of Mr. Preece, were short notes. Mr. Kapp exhibited an interesting set of curves showing the performance of alternate-current motors.

The International Discussion on Electrical Standards was a great disappointment to many of the members, to all, in fact, except the members of the committee, for it was carried on behind closed doors, and only a report was "presented;" that is to say, it was given in a short verbal summary by Mr. Glazebrook, none of the arguments or reasons which led to its adoption being disclosed. We hope, however, to be able to furnish our readers, many of whom take a keen interest in the matter, with an account, unofficial, but on the best authority, of the proceedings of this committee.

Another disappointment was the expected discussion on a National Physical Laboratory. A large audience of about 115 members—that is, about four times as many as were usually to be found at the meetings—were interested in hearing Dr. Lodge's scheme; Prof. von Helmholtz's account of the Reichanstalt, the Government laboratory at Berlin; and a description by Dr. P. H. Schaute of the physical laboratory recently established at Gröningen, in Holland. Lord Kelvin made some brief remarks, and Prof. Rücker made a few observations about the work done at Kew. Prof. Fitzgerald, Sir G. Stokes, and Prof. Ayrton took part in the discussion, in which very few important arguments were adduced, and Dr. Oliver Lodge replied. The endowment of research, and this particular research after an endowment, appear as far off as ever.

It is a pity that Prof. Blyth, who has been experimenting seriously with windmills for driving dynamos, has not been able to arrive, as yet, at any idea of what Mr. Swinburne would call the time-integral of the power, or, in plainer language, the total horse-power hours that may be developed in a twelvemonth by a windmill of given dimensions and construction. In reply to an inquiry after the reading of his Paper at the British Association on Friday last Prof. Blyth could only say that during one week in May his mill drove a 4-horse power dynamo at half-power, and on two or three days, it ran "much faster," occasionally developing the full output. The fact that "13 cells were kept charged" is hardly a measure of success; and yet wind-power is too cheap to be overlooked. We have remarked on a former occasion that the question of first cost really decides the question, rather than the irregularity, which is a question of storage. In spite of all the gold medals that were awarded at the Crystal Palace "for batteries" the charging of accumulators is a poor way of storing energy. We have already suggested in these columns that wherever space for storage and a sufficient fall can be obtained, there is probably no better way of storing the power developed by a windmill than pumping water into a reservoir; a pump with a variable stroke would enable a mill to do good work both in a light breeze and in a stiff gale. Perhaps a better way would be to use a set of concentric or parallel plungers arranged in connection with a governor, so that in a light wind only the one would work, the others being locked to the barrel. With stronger wind, the other plungers would become locked to the connecting rod, and thus nearly the whole available power might be used with a nearly uniform, or with the most

Digitized by Google

efficient velocity of the sails. We understand that Prof. Blyth finds it possible to run an arc lamp fairly steadily with his windmill.

Prof. Hele Shaw's report on "Graphic Methods" will no doubt be consulted with great interest by electrical engineers when it is published; and judging from the abstract, which we hope to print in an early issue, not only the copious bibliography of the subject which forms a large portion of its contents, but the valuable generalisations of graphic methods which it contains will be greatly appreciated. Graphical methods are generally invented only when they are wanted, often by men whose algebra is too rusty for analytic work, and very little systematic arrangement has been attempted. The subject has, in fact, received next to no really scientific treatment.

It would be a convenience if some short name could be found for vacuum tubes without electrodes. These were referred to by several speakers at the British Association, both in Papers and in discussion. They have been used for years; but it will be conceded, even by those who, like Dr. Bottomley, have used them largely, that before Tesla's experiments not much attention had been paid to them, and it can be denied by none that he has outstripped all in the brilliant effects which he has produced. The word "vacuum tube" has become more common than "Geissler tube"; but why not use the name "Tesla tube" for one without electrodes, leaving vacuum tube to include both kinds?

The arrangements and organisation of Sections A and G, which are practically the only Sections of the British Association which deal with electrical subjects, have been no better than usual. The Secretaries who have acted in former years have been assisted by several local members, four being allotted to Section A, which deals with mathematical and physical science, and five to Section G, which deals with mechanical science. No attempt was made to give more than a suggestion of the subjects which would be dealt with on different days; but other Sections, such as the Geographical and Geological Sections, published very full lists of the proposed Papers and the names of the authors. No pressure had been brought to bear upon authors to send in their Papers before the meeting, and but few abstracts were to be obtained. The details which would go to make the task of sitting for hour after hour in these meetings endurable, such as the systematic supply of Abstracts or Papers to those who want them, the proper darkening of the room during experiments, the provision of proper chalks, the announcement during discussions of the names of speakers, and the suppression of talking and other unnecessary noises, are simply ignored. Notice boards outside each room were provided as usual for announcing the number of the Paper which was being taken at any time; but, as usual, these were hardly ever used, nor were they even employed to announce that the meeting had been adjourned.

The Sectional Meetings of the British Association, so far as Physics and Engineering are concerned, appear to be intended mainly for the members of the committees. Outsiders are invited and indeed urged to send Papers, and are allowed to take part in the discussions; but, although it is they who contribute the bulk of the funds, their convenience is neglected, and but little trouble is taken to render the proceedings attractive to them. The committees seem to be afraid of enforcing any of the ordinary regulations of scientific societies, and allow one or two eminent men, who cannot be bothered in holiday time to write their communications, to prevent any orderly arrangement of Papers. As to the programme for the next day, the members of committees can, if they care to attend, inform themselves about it in good time, and the Secretaries are of course acquainted with it; but the programme for the day, as far as outsiders are concerned, is not published until the same morning, causing the greatest inconvenience to the ordinary members. There is no reason why it should not be posted in the room, and in the reception room as soon as it is decided upon.

There are, however, Secretaries and Secretaries. The work done by Mr. Glazebrook and by Prof. Hele Shaw in the preparation of the reports of sub-committees is comparable with the best work of any scientific societies. These reports have a most important and lasting value, and they are in strange contrast with the advertising Papers and half-finished communications from students and faddists which often occupy the time of the Sectional Meetings. A description of a flying machine may appeal to a crowd of holiday makers, but such sketchy performances are hardly a fitting foil to the solid work of the reports, which is apt to be lost sight of among them.

Considering that the City and South London Railway is not only a new concern, but is a new concern worked in a novel manner, the progress it is making towards a steady dividend-earning position is sufficiently rapid. Compared with the corresponding period of 1891 there has, during the past half-year, been a 20 per cent. increase in the number of passengers carried, and a 9 per cent. increase in the gross receipts, while expenses are less by some 3 per cent. The best evidence that the Company is being managed on sound lines is that afforded by the items grouped together in the accounts in Abstract B., "Locomotive and Generating Power." Here we see that in spite of an increase of nearly 9 per cent. in the train mileage, viz., from 174,435 for the first half-year of 1891 to 188,944 for the corresponding period of this year, the running expenses have come down by 13 per cent., viz., from £6,148 to £5,360; wages and coal both showing substantial savings. The locomotive expenses, which were 9d. per train mile when the line commenced working, are now only 7·7d. The happy idea of building a gallery round the engine-room at Stockwell and levying a tax upon the curiosity of the public may be commended to central-station companies in quest of a dividend.

The financial result of the first quarter's working of the Brighton municipal electric light undertaking is not altogether unsatisfactory; especially in view of many of the circumstances which attended the inception and carrying out of the

Digitized by Google

scheme. The sale of electricity at 7d. per unit, together with meter rents, realised some £840, while the total outgoings amounted to £582; leaving a profit on the first quarter of £250, after making some provision for bad debts. This profit, it is true, is converted into a deficit of £283 10s. 6d., owing to the necessity of setting aside moneys for interest and sinking fund. It is also true that interest on capital during construction amounting to £370 has been charged to capital account, as well as £2,100 under the head of general expenses. But this mode of procedure is not peculiar to the Brighton undertaking, and on the whole there seems to be good grounds for anticipating before long a more evenly balanced state of things.

Personal.—Mr. W. H. Brownlee, of Glasgow, has been appointed electrical engineer for the city of Dundee.

Bristol.—Owing to the bricklayers' strike it is not now anticipated that the supply of electricity will be available this winter.

Durham College of Science.—The Autumn Session of this College commences September 26th. For further particulars see our advertisement columns.

River Cables.—The Indian Telegraph Department have recently laid three more cables across the Irrawaddy. There are now in all eight cables crossing it.

Colchester.—At the last meeting of the Town Council it was agreed that the Lighting Committee should be empowered to take proceedings for obtaining a Provisional Order.

Southport.—The Gas Committee have recommended that application be made to the Local Government Board for power to borrow £28,000 for the purpose of carrying out an electric lighting system.

Appointments in Cable Companies.—In the list of appointments given last week that of Mr. William Hibberdine to be Traffic Accountant of the Eastern Telegraph Company, in place of the late Mr. Lewis Wells, was inadvertently omitted.

Coast Telegraphic Communication.—The Post Office cable steamer *Monarch* arrived at Scilly on Tuesday last week, and commenced the work of connecting the coastguard stations at St. Mary's, St. Agnes, Bryher, Tresco, and St. Martin's.

Electrical Standards.—On p. 372 (line 22 from the top) of our last issue, "the pull between two parallel surfaces joined by a weber is $10^{16}/6\pi$ dynes, or 400,000 tons," should read as follows: "The pull between two parallel surfaces *of one square centimetre area.* . . ."

Electric Lighting Notices.—The Works Committee of the Limehouse Board of Works have had under consideration the notice of the City of London Electric Supply Corporation, that they intend to apply for a Provisional Order. They recommended that the application be opposed.

Yarmouth.—At the last quarterly meeting of the Town Council the Town Clerk reported that he had received tenders for an electric light installation for the town from several firms. The tenders varied between £5,000 and £6,000 to £23,000. These were referred to the Electric Light Committee.

Berlin.—The Allgemeine Elektricitäts Gesellschaft of Berlin are proposing to erect a central station in the suburbs of Berlin. The kilowatt hour for lighting purposes will be charged at the rate of 6¼d., and for power purposes at the rate of 1¼d. Rebates will be given to large consumers. Separate meters will be installed.

Melbourne.—The contract for supplying the machinery and apparatus for the electric light installation has been secured by the Thomson-Houston Electric Company, and that for supplying the boilers by the Babcock-Wilcox Company. The cables and wires are, our readers will remember, to be supplied by the International Okonite Company.

Barnsley.—At a recent meeting of the Town Council the consideration of the recommendations of the Park and Lighting Committee, that the electric light should be installed on a site in Beckett-square, at an estimated cost of £18,382, and that application should be made to the Local Government Board for sanction to borrow the said sum, was deferred.

Tanning by Electricity.—A company has been formed at Barcelona, says *Industries*, to establish a tanning factory by electricity on the Groth system. Should the new factory prove successful many others will doubtless be established in Spain, particularly at Valladolid, Seville, Saragossa, Valencia, and other such towns, where the tanning industry is now carried on.

Blackburn.—The Gas Committee of the Town Council have ordered the preparation of detailed estimates, plans and specifications for the proposed electric lighting works, and have decided to recommend the Town Council to make application to the Local Government Board for sanction to the borrowing of £50,000. A suitable site for a central station is also to to be selected.

Obituary.—We regret to record the death at Christiania, in his 74th year, of M. Carsten Tank Nielsen, Director-in-Chief of Norwegian Telegraphs. M. Nielsen was the *doyen* of the International Telegraph Conference, having attended the first Telegraph Conference held in Paris in 1865, and he was presented with the order of Commander of the Legion of Honour of France at the last Conference, held in Paris in 1890.

Aluminium Plating.—With reference to the statement which Mr. Swinburne makes in his Paper on "The Problems of Commercial Electrolysis," that "it seems to be impossible to deposit aluminium from any of its solutions . . . ." (see *The Electrician*, August 5th, p. 368), M. Van Beete, of the Maatschappij tot Exploitatie van De Brakke Grond of Amsterdam, sends us an iron screw plated with aluminium in aqueous solution at ordinary temperature.

Earth Currents.—Mr. C. P. O'Reilly writes us from Bombay to the effect that earth currents were on the telegraph wires in that neighbourhood on July 12th, 13th, 16th and 17th. The currents were most felt on wires running S.E. and W.N.W. and occasionally lasted for several hours at a time, sometimes attaining a strength of 10 milliamperes. Our correspondent calls attention to the fact that these disturbances took place at the same time as eruptions at Etna and Sangir, and he states that a high wind and squally weather also prevailed.

Lightning.—An inquest was held at Fareham last week with regard to the death of a bricklayer from lightning on Saturday, 30th ult. On the same day a storm passed over Wimborne; and some sheep were killed. They were standing near a fence composed of stout oak posts and wire. Many of the posts, which were eight inches thick, were shattered in the most extraordinary manner. Splinters of the wood were scattered 40 yards from where the posts were standing, and a staple used to fix the wire to the posts was driven 45 yards from the wire. Some of the posts were split clean in two, whilst others had furrows ploughed in them.

Electricity in Mining.—On Friday last week the annual general meeting of the South Wales Institute of Engineers was held at Cardiff, and Mr. Albion T. Snell opened a discussion on a Paper on Electrical Work in Mines, read by him at a previous meeting. In the course of the discussion, Mr. Archibald Hood said he did not think there was a more important subject they could discuss than the transmission of power underground by electricity. Since he had employed it he had determined to increase it. He had half-a-dozen pumps working underground by electricity, and the results in every case were highly satisfactory. There was a wide field of application for electricity, and he had no doubt the time would come when engineers would succeed in preventing anything like liability to explosion.

Glasgow.—The Gas Supply and Electric Lighting Committee have presented their annual report and balance-sheet to the Town Council for the year ending May 31, 1892. After making the usual provisions in regard to sinking fund,

Digitized by Google

&c., and depreciation, there remains a deficiency on the year's operations of £26,000. The Committee recommend that the price of gas should be increased from 2s. 6d. to 2s. 9d. per thousand. No accounts with regard to the electric lighting undertaking are presented by reason of its recent commencement. It is hoped that a supply of current on the low-pressure system will be available before the winter sets in.—The Town Council have accepted the tender of the Brush Company for the supply and erection of series arc dynamo machines and lamps for public lighting, in accordance with the specifications drawn up by Prof. Kennedy; and the tender of Messrs. Easton and Anderson for the engines.

Electric Traction in Germany.—In regard to the statement published on page 161 of our issue of June 17th, to the effect that the then recently opened electric tramway at Bremen was the first in Germany to be operated upon the overhead trolley system, the Allgemeine Elektricitäts Gesellschaft of Berlin write to us to point out that this is not the case, as the Halle tramways have now been worked with an overhead wire for a considerable time, and with such success that important extensions are now in progress. In February of this year also the electric tramway at Gera, equipped by the same company for Messrs. Vering and Wächter, was handed over to be worked. The satisfactory results of working these two lines electrically have raised electric traction in Germany, they inform us, above the experimental stage, and created so much confidence that the Allgemeine Elektricitäts Gesellschaft have now in hand two large lines—one for the Berlin Lokal und Strassenbahn Gesellschaft, situate at Chemnitz, and the other, which has a total length of about 18 miles at Breslau, for the Aktiengesellschaft Elektrische Strassenbahn, Breslau.

The Action of the Electric Discharge on the Atmosphere.—In a recent issue of *Wiedemann's Annalen* Dr. V. Lepel publishes an account of an investigation of his on the oxidation of nitrogen by the electric spark, and his conclusions are interesting in the light of Prof. Crookes' theory, referred to in an Editorial Note, on p. 211 of our issue of July 1st. It is well known, says Dr. Lepel, that the passage of high-pressure electric discharges through damp air is accompanied by the formation of small quantities of nitrous and nitric acids (HNO_2 and HNO_3), which form ammoniacal salts in air. The first action of the discharge seems to be the production of nitric oxide (NO), which is immediately converted into peroxide (N_2O_4). This latter reacts on the vapour of water, to form nitric acid, liberating nitric oxide. Nevertheless, it has been observed that sparks passing through gaseous oxides of nitrogen decompose them into their original elements. Hence, as a consequence in a given space, a limit is soon reached when no more nitric acid is formed. Dr. Lepel has experimented with a slow current of air, under different pressures and with different kinds of discharge, and has succeeded in increasing the production of nitric acid to 10 per cent. of the total quantity of air employed. He considers it probable that by means of high-pressure discharges nitric acid may be made from the atmosphere on a commercial scale.

Oldham.—An inquiry was held at Oldham on Friday last, before Colonel Hasted, R.E., the inspector appointed by the Local Government Board, in reference to the application of the Corporation for borrowing powers not exceeding £40,000 for electric lighting purposes. The Town Clerk said that on April 28, 1887, the Corporation acquired a plot of land adjoining the railway, situate at Rhodes Bank, which they propose to utilise for the electric lighting station. Nothing further was done by the Corporation until the Session of 1890, when they obtained a Provisional Order. In February of this year the Corporation retained Prof. Kennedy as their electrical engineer, and he had devised a scheme for the Corporation. The plant proposed to be put down would supply simultaneous lighting for about 2,500 lamps of 8 c.p. each. The system was to be two-wire low pressure. The engineer's estimate of the cost of the works to be carried out forthwith was, exclusive of land, £21,000. The Corporation anticipated that close upon 2,000 lights would be taken up immediately. The Corporation thought thirty years would be a reasonable time in which to be allowed to repay the money. Prof. Kennedy then explained details as to the site of the works and the cost. The scheme was so arranged that the two-wire system could be changed to three-wire if the demand required it. The cost he estimated as follows:—The plant, including everything stationary, £8,800; the mains, £5,600; the buildings, £6,000; the meters £600. The inquiry then concluded.

Brighton.—At the meeting of the Town Council on Saturday last the Lighting Committee presented their statement of accounts relative to the first quarter's working of the electric lighting system, from September 15th to December 31st, 1891. The sale of electricity, at 7d. per unit, realised £831. 10s. 3d., and £8. 5s. rent of meters brought the total revenue up to £839. 15s. 3d. The cost of generation amounted to £391. 18s. 10d., and management expenses amounted to £173. 3s. 7d. Rates, taxes, and insurance raised the total outlay to £582. 5s. 11d. After setting aside a sum of £7. 9s. 4d. for bad debts, there remained a balance of profit of £250. Two sums of £290. 18s. 6d. and £242. 12s. were, however, required respectively for interest and sinking fund in respect to the original outlay. These two sums amounted to £533. 10s. 6d.; and after deducting the £250 brought forward from the revenue account, there remained a deficiency of £283. 10s. 6d. Alderman Moon explained the accounts, and stated that they made a start with only four customers, but gradually raised the number during the quarter to 82, for the supply of 2,374 lamps; but it had to be borne in mind that some of those were only supplied for three or four days at the end of the quarter, so that it was manifestly unfair to draw any conclusions from their first quarter's trading. They were now supplying 3,715 lamps out of the 10,000 provided for, and he had perfect confidence in saying that in two years' time they should be working at a profit, enabling them either to apply a surplus to the rates or to reduce the cost. After this explanation all opposition was withdrawn, and the accounts were adopted *nem. dis.*

The Electric Lighting of Railway Carriages.—We are informed that a contract has been entered into between the Railway Electric Reading Lamp Company and the Metropolitan District Railway Company to instal upwards of 10,000 reading lamps in the carriages of the District Railway. We are given to understand that similar contracts are being negotiated with other railway companies. It is not intended at present to displace the gas lamps in use in the roofs of carriages, but to provide a separate light for passengers desiring to read. The mechanism by which this will be accomplished is contained in a box 5in. by 3in. Upon introducing a penny into the slot at the top of the machine and subsequently pressing a knob, an electric light is obtained which burns for about half an hour, at the end of which time it is automatically extinguished, but can be relighted by the insertion of another penny. The light, which is of about 3 c.p., is concentrated by a shaded reflector, which may be turned within certain limits, so that the light may be directed to suit the position of the passenger. The instrument is so arranged that in case of a failure in the supply of electricity, the machine automatically returns the coin to the operator. Another feature is that, should the lock of the apparatus be tampered with, a bell is automatically set ringing in the guard's van. It is proposed to place these lamps under the hat rails in railway carriages, so that the passengers seated in the corners, and thus farthest from the roof light, may be able to provide themselves with additional illumination. The whole of the lamps placed in one carriage are supplied with current from an accumulator placed under one of the seats of the carriage. The lamps are to be worked at 12 volts, and will require about 0·75 ampere. The accumulator has been specially designed for the work, and consists of six cells, coupled in series, having a capacity of 72 ampere hours. A charging station is to be erected at Mill Hill Park, on the District Railway, and sidings are to be made in the station for the reception of a number of trucks on which the accumulators will be charged and removed. Early in the morning trucks containing the charged accumulators will be forwarded from the charging station to the various distributing termini, where they will be changed as required during the day; and then at night the trucks will return with the exhausted batteries.

PROF. EWING'S MAGNETIC CURVE-TRACER.

At his evening lecture before the British Association on Monday, and again in Section A on the following day, Prof. Ewing exhibited his apparatus for automatically drawing magnetisation curves.

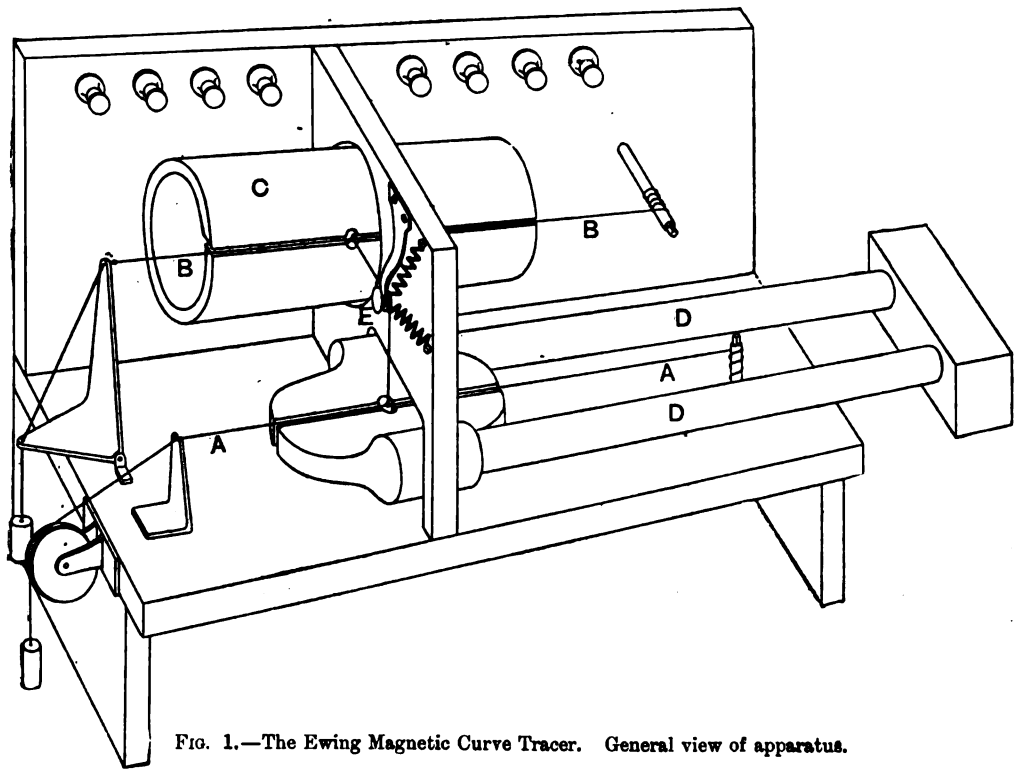

FIG. 1.—The Ewing Magnetic Curve Tracer. General view of apparatus.

This instrument is a practical magnetic tester, which will allow the makers of dynamos or transformers to test their iron with the greatest ease, and will allow different samples to be compared for permeability, hysteresis, and other magnetic characteristics with the rapidity and simplicity necessary in workshop tests. The instrument combines, in a single piece, a novel form of galvanometer with a novel form of magnetometer, and the indications of both are given by a single mirror, which receives a horizontal motion proportional to the magnetising force, and a vertical motion proportional to the magnetisation. A spot of light reflected from the mirror in the usual way traces out the curve of magnetisation on a screen consisting of a sheet of squared paper. The mirror is so dead beat with respect to both of its component movements that a cycle of magnetisation may be gone through in a fraction of a second.

The principle of the apparatus will be seen by reference to Fig. 1, which, it should be understood, is a mere diagram, and does not exhibit the details of construction. E is the mirror which is mounted on a single needle point in such a way that it has two degrees of freedom for deflection. It receives azimuthal movement from the wire B B, which is lightly stretched in a narrow gap in a magnet C. This magnet is a piece of iron pipe with a longitudinal slot cut in it, and is magnetised by means of a longitudinally wound coil, so that the lines of force jump across this slot, in which the wire B B is strung. The mirror at the same time receives altitude movement from the wire A A, which is stretched in a narrow gap between the pole-pieces of a magnet D D. The magnet D D consists of the samples which are to be examined, united at the back end by a yoke-piece of soft iron. A constant current is kept up in the wire A A, and it there-

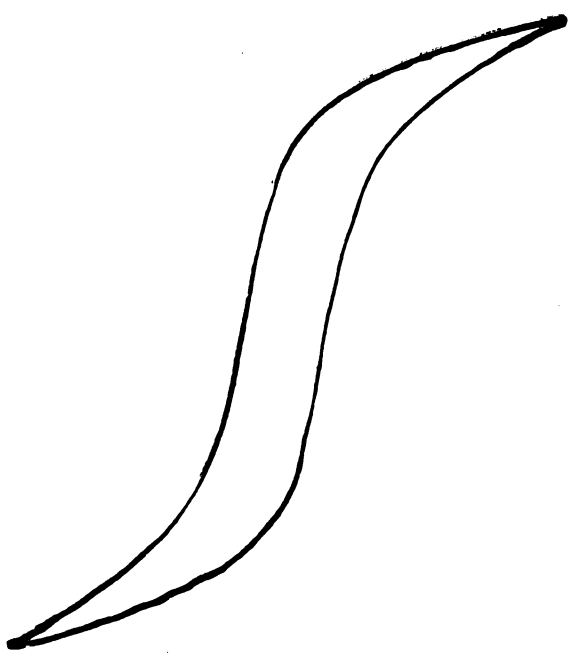

FIG. 2.—The Ewing Magnetic Curve Tracer. Sample plain hysteresis curve.

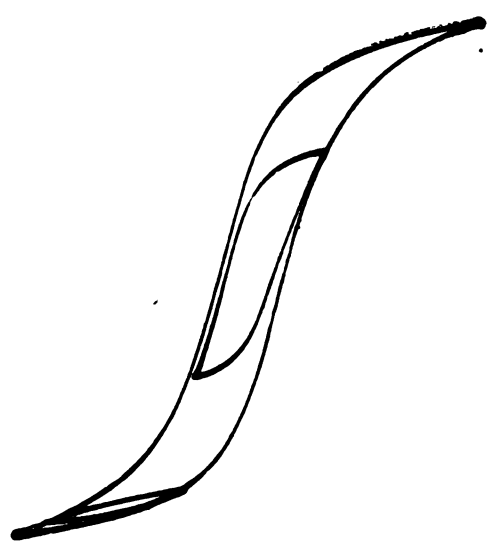

FIG. 3.—The Ewing Magnetic Curve Tracer. Sample hysteresis curve with loops.

Digitized by Google

fore sags up or down proportionally to the variations of magnetism in the rods D D. These rods are surrounded by magnetising coils, and the current for them passes also through the wire B B, which, as has just been said, is stretched in a constant magnetic field. It consequently sags out or in, giving horizontal deflection to the mirror, by amounts which are proportional to the magnetising force in the coils of D D. Hence, to describe a magnetising curve for the rods D D it is only necessary to apply a gradually-increasing current to the coils of D D, when the mirror takes vertical movement proportional to the magnetism and horizontal movement proportional to the magnetising force, and by reducing the current to zero, reapplying it, reversing it, and so on, all the magnetic characteristics of the material are rendered obvious at a glance.

Prof. Ewing has arranged the apparatus so that a complete cycle of magnetisation—the usual cycle of double-reversal—can be gone through in one-tenth or even one-twentieth of a second; and this allows the spot of light to trace a curve which appears as a continuously luminous line—an experiment which was shown in his lecture. In the use of the instrument as a practical magnetic tester it will, however, generally be preferred to trace the curve more slowly, following with a pencil the movement of the spot of light, and so obtaining a permanent record. A simple variation in the form of the pole-pieces and yoke allows sheet-iron or wire to be tested instead of solid turned rods. It was shown by actual experiment at the lecture that a complete cycle could be obtained for a given specimen in a few seconds; then another specimen was put in, and its curve projected just above the previous one, so an immediate and at the same time complete comparison of the two could be made.

The curves shown in Figs. 2 and 3 are reproduced from photographs of magnetic cycles taken by means of this instrument, using laminated iron specimens, the light spot being reflected directly on to the sensitive plate. The plain cycle (Fig. 2) is one of a series which were taken at the rate of two cycles per second; the plate was exposed 15 seconds, so that the curve was traced over 30 times. The little ripples due to the inertia of the working parts reproduce themselves in the same places every time. Fig. 3 is a photograph taken while the current was varied by hand in such a way as to superpose two smaller loops on a main cycle of reversal.

In exhibiting the instrument in Section A, Prof. Ewing points out further uses to which the apparatus could be adapted as an exceptionally dead-beat galvanometer, and also as a phase-meter and as an analyser of alternate currents.

SECONDARY BATTERIES IN USE AT THE CENTRAL TELEGRAPH OFFICE, LONDON, FOR TELEGRAPHIC PURPOSES.*

BY W. H. PREECE, F.R.S.

In a Paper entitled "The Use of Secondary Batteries in Telegraphy," communicated to the British Association at the meeting held in Montreal, in 1884, I gave an account of a series of experiments which had been carried on during the preceding twelve months, to determine the suitability of secondary batteries for telegraphic purposes. In the same Paper, after giving a number of calculations as to the financial side of the question, I ventured to predict that secondary cells would soon be made the most economical of the sources of electrical energy for this purpose.

Since that time the use of secondary batteries has been extended, and for the past seven years they have been used to supply current to two large groups of circuits, one group consisting of 110 single needles, and the other of 100 Morse inkers and sounders.

To provide a ready means of replacing the battery in case of failure, the leads from the working and reserve cells, which are placed in the basement, are first led up to the test-board in the instrument room, and there joined to a switch, thence the leads are again led to a test-board in the battery room, where the two groups are split up into sub-groups of ten circuits each. The connections are made in this manner for two reasons, first, for facilitating a change of a faulty battery; and, second, to prevent a general stoppage of the whole group in the event of a short circuit at any of the instruments; the resistance of the leads between the instruments and the sub-dividing connections in the basement being sufficient to prevent more than three amperes being taken from the battery by any one of the instruments even when a short circuit is on. To prevent any damage to the instruments, or risk of fire, fuses are placed in the battery leads at each instrument. The circuits on the groups mentioned are all metropolitan, and are all, approximately, of the same resistance, no equalising resistances being, therefore, necessary. The current in each circuit ranges between 17 and 20 milliamperes. The E.M.F. for the single needles is 20 volts; ten cells positive and ten cells negative, with earth in the centre. For Morse working, the E.M.F. is 18 volts. The connections are shown in Fig. 1.

In addition to these two groups another set of 22 cells has been in use since 1889, supplying current for driving the motors of the Delany Multiplex Distributors. Each of these motors requires a current of about 0·12 ampere, and there are ten of them at present driven from this source. Fuses are placed in the leads to each motor. There is no spare set for this work. A considerable extension of the accumulator system has recently been made, advantage being taken of the transfer of all the Continental service to the General Post Office building in St. Martin's-le-Grand. This transfer was made on October 17, 1891, and since that date the whole of the Continental circuits have been operated by currents from secondary cells. There are 59 of these Continental circuits, and as they are of various lengths, some requiring repeaters in England, whilst others go direct to the Continent, a somewhat different arrangement has been adopted. In addition to these varying conditions, it was found impossible to use the same polarity to all countries. The German, Dutch and Belgian lines taking positive, and the French negative. It was also necessary to provide an arrangement which would cause the stoppage of the minimum number of lines should a main fuse be burned or a battery fail.

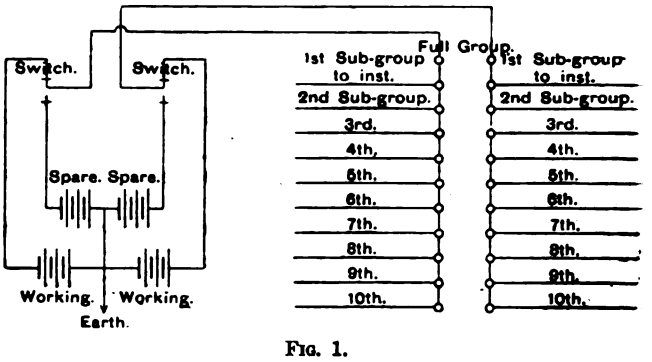

FIG. 1.

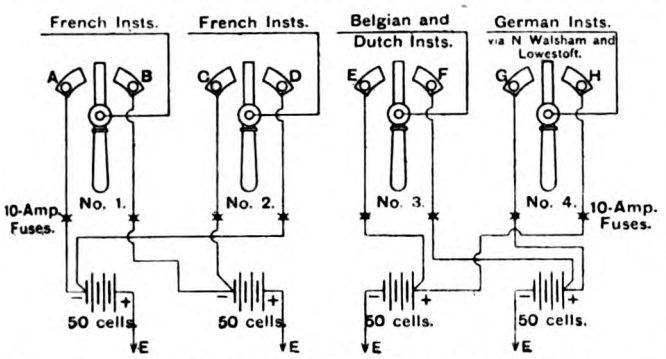
The 59 lines are divided into four groups, but as the force required for these long lines is 100 volts it is evident that the risks of allowing a dangerously heavy current passing out from the instrument to line, should it make earth near the sending station, is increased. To provide against this, resistances of 100 ohms are placed in the battery leads at each instrument, so that it is absolutely impossible that more than one ampere can flow even with earth on the line close up to the instrument. Independent 3-ampere fuses are also fitted to each instrument, to prevent any damage to lines or instruments, should the safety resistance be short-circuited. As it is sometimes necessary to put repeaters in on the English side of the cable on some lines which nominally work direct to the Continent, the resistance blocks on several of the instruments are wound to 1,000 ohms, and fitted with a switch which enables either 100 ohms or 1,000 ohms to be inserted in the battery circuit, and thus the current is kept constant. In addition to the independent 3-ampere fuses, main fuses to break at 10 amperes are placed on each group of circuits in the accumulator room.

* Paper read before the British Association at Edinburgh, in Section G, August, 1892.

Digitized by Google

The arrangement of the connections in use on the Continental lines is shown in Fig. 2. All the cells are kept well charged, and the E.M.F. is not allowed to fall below 1·95 volts per cell. Where spare or reserve sets are provided the charging is carried on at any convenient time, and on those where no



100 ω resistance in each Branch Lead to French, Belgian and Dutch Instruments.
100·0 ω „ „ „ „ German Instruments.

FIG. 2.—Connections of Secondary Cells for the Continental Gallery.

spare sets are in use the charging is done at night, when the minimum disturbance is caused by the slight increase of E.M.F., which is inseparable from simultaneous charging and working. Accumulators are also used for working the Paris telephone circuits. Their E.M.F. is so constant that they are found to be eminently adapted for the purpose.

ON THE EFFICIENCY OF TRANSFORMERS.*

BY M. VON DOLIVO-DOBROWOLSKY.

(Concluded from page 371.)

The cardinal virtue of the transformer is unquestionably its high efficiency. But efficiency, when applied to transformers distributed in installations or in central stations, has a different meaning to that usually accepted in the case of dynamos and motors. The loss which takes place in a transformer must be distributed over the whole daily working period, probably twenty-four hours, during only a relatively short portion of which time, even in winter, does the full load come on. By the average efficiency of a transformer we are to understand, then, the ratio of the all-day useful output in watt hours to the watt hours delivered to the transformers. It is true that by this mode of computation the efficiency will depend upon the curve of current consumption during the day, the unfavourable effect of which the transformer builder cannot help. It is, however, possible to plot a curve of the mean all-day consumption for separate localities or towns, and on that basis to determine approximately the all-day efficiency of the transformers, and to arrange their construction accordingly. Figs. 6 and 7 illustrate, for example, the current consumption respectively in Berlin and in a provincial town; in the latter there is no electric motor work during the day-time. From an examination of these load curves we see that the efficiency of the transformers at maximum load has a barely perceptible effect upon its average efficiency, and that the chief trouble is the loss at light loads.

The losses in the transformer are twofold: (1) those due to the copper resistance, called the "copper loss"; (2) those that take place in the iron, and, as mentioned above, caused, for the most part, by hysteresis, and called the "iron losses." The copper losses increase as the square of the current; and if the exciting current is small, as is usually the case, we may approximate proportionality between current and load. It comes, then, to this—that the copper losses rise and fall as the square of the load. For instance, if the copper loss at full load is 100 watts, at half load it will be only 25 watts; at one-tenth maximum load only 1 watt. The copper loss has, therefore, but little effect upon the average efficiency of the transformer, light loads only being of account in this connection. The iron losses, however, like the magnetism, are constant for the whole range of the transformer's capacity. They become, therefore, the more important the smaller the load, and *vice versâ*; so that in order to obtain high average efficiency during the day-time, it is necessary to keep the iron losses small.

A transformer may always be graphically illustrated, as in Fig. 8, namely, as two tightly interlocked links, one of copper, the other of iron. It is not possible to increase the cross-section of one of these links without increasing that of the other. The misfortune with transformers is that we cannot increase the copper cross-section, and so reduce the resistance and copper losses, without at the same time increasing both the volume of the iron and the iron losses. But the net outcome of this is that, as the copper losses only slightly affect the efficiency, it is possible, by allowing a comparatively large

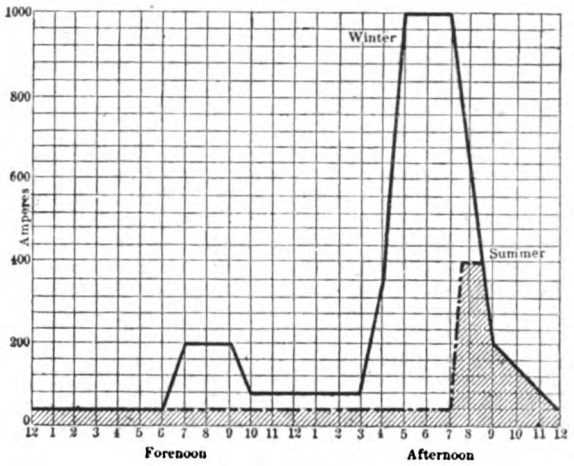


FIG. 6.

copper loss, to do with a small volume of iron, and thereby obtain a high all-day efficiency. The only disadvantages of large copper losses are that in central stations with a growing load an additional electromotive force of several per cent. must be provided. This would tell somewhat against such a device, were it not that we are accustomed to this with almost all systems of the distribution of

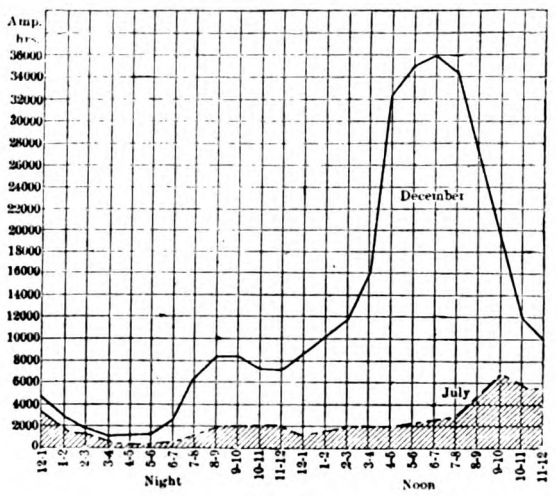

FIG. 7.

electricity. Continuous-current stations are more easily operated with a pressure on the feeders some 20 per cent. higher than the distribution pressure. Moreover, it seldom happens that less than 2 per cent. or 3 per cent. loss takes place in the long-distance circuits of a high-pressure alternating-current system; this, with the addition of the 2 per cent. loss in the transformers, gives a total loss of volts

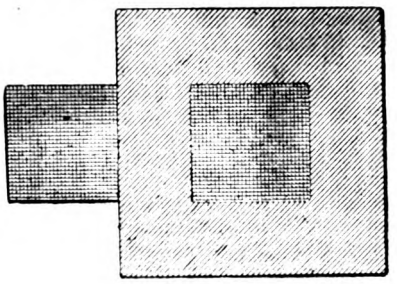

FIG. 8.

of at least 5 per cent., apart from the small fall of volts due to the magnetic leakage of the transformers. This 5 per cent. has even now been compensated for. Why, then, is it not possible to make up for more, for instance, for 7, 8, or 10 per cent.? This fall of volts, moreover, is still smaller than that which usually obtains on continuous-current systems, and regulation of some sort cannot

* A Paper read before the Electrotechnic Society of Berlin, March 22, 1892.

Digitized by Google

be dispensed with in any case. The idea that it is sufficient with an alternating-current system to keep the station voltage constant has long been abandoned. I propose, therefore, to break with the traditional 2 per cent. potential loss in transformers, and to assume something like 4 or 5 per cent. as the normal, especially where it is not the maximum efficiency but the all-day efficiency that is of importance. More coal may be saved by this means than one would imagine.

A further question is whether iron losses may not be lessened by certain modifications in the constructive arrangement of transformers. If we have a certain quantity of iron, and a given magnetic density, we shall always have the same iron loss for the same frequency. This loss is independent of the shape of the iron. How shall we arrange our iron in order to obtain from it the largest possible amount of transformed energy? The answer to such a question cannot be other than that the given quantity of iron must be disposed, so far as possible, in such manner as to provide as much room as possible for the copper winding. As a matter of fact, the "window," or the opening for the winding, is in the case of thick rings disproportionately small. Nor must we go too far in arranging the iron in a thin broad ring, as, in consequence of the ever-increasing periphery of the copper coils, the output increases at a slower rate than the weight of copper, and the transformer would become too expensive. Nevertheless, it is always advisable to give the iron such a form that a lot of copper can be employed, for the price of the transformer might easily be more than double the present average price, if a material saving in running costs could be effected thereby. As an increase in the cross section is accompanied by a less rapid increase of periphery, large transformers can be built more efficiently than small ones. It is impossible to give too urgent a warning, therefore, against the American practice of using a transformer in every house, be it ever so small. The saving in wire is nothing as compared with the increased running costs. In distribution systems, where economy is of prime importance, only a few transformers of under 5 kilowatts should be employed; and I believe that soon the average size of a transformer will be at least 20 kilowatts. The objection that very large transformers have not sufficient cooling surface I would meet by citing the example of the largest transformers ever made, namely, those on our Lauffen-Frankfort installation. These transformers have been at work for days at a time, as was the case when the trials of the Testing Committee were being carried out, and their temperature did not rise more than 40° C. This was so with the transformers of the Allgemeine Electricitäts Gesellschaft, as well as with those of the Oerlikon Company.

I again take the liberty of comparing these new views on transformers with those hitherto generally accepted:—

(*a*) *Old View.*—The magnetic circuit must, if possible, have little resistance; the iron must be short, thick, and, if possible, without joints. *New View.*—The magnetic resistance is of little importance; joints may be made in view of constructive considerations (indeed, they are desirable at times in order to oppose the electrostatic capacity of the circuit); the iron cores must be relatively long and thin, in order to leave plenty of room for copper.

(*b*) *Old View.*—The copper must, if possible, be surrounded with iron—it should even be embedded in iron where possible—in order to save copper. *New View.*—The iron must, if possible, be surrounded with copper, in order especially to save iron.

(*c*) *Old View.*—The transformer must be self-regulating, and to this end the coils must have as little resistance as possible. *New View.*—Do not try to obtain self-regulation, as this is illusory, owing to the losses in the circuit. The resistance of the transformer, so long as it is not excessive, has little effect upon the average efficiency, and if we increase the copper resistance with the object of reducing the iron mass, the economy may even be improved.

In order that your faith in the possibility of thoroughly good transformers, that will also work economically at light loads, may be strengthened, and by way of illustrating my principles, I will bring forward some actual examples, and these examples refer to transformers specially designed by the Allgemeine Electricitäts Gesellschaft for distribution purposes. Fig. 9 represents an alternate-current transformer of 3,500 watts capacity at 80 alternations, transforming down from 1,000 volts to 100 volts. The actual iron cross section amounts to 42 square centimetres, after making allowance for the insulation. Number of high-pressure turns, 3,600; low pressure, 360. The high-pressure copper wire is 2·3 mm. diameter (4·1 square mm. cross section), and the low pressure 5 × 8 mm. rectangular wire (cross section owing to rounded corners 38 square mm.). The resistances of the two windings amount respectively to 9·0 and 0·064 ohms when warm. This gives a total copper loss at full load of about 5·3 per cent. The weight of copper on the transformer comes to about 120 kilogrammes. The iron core 440 mm. long, with cross pieces 350 mm. long, suffices to take the above amount of wire with plenty of insulation, &c. The weight of iron is about 50 kilogrammes. With a density of 4,000 lines of force, and looking at the curve in Fig. 5, which may be considered as referring to moderately good iron, it follows that there is a no load loss of 50 watts = 1·4 per cent. of the transformer maximum

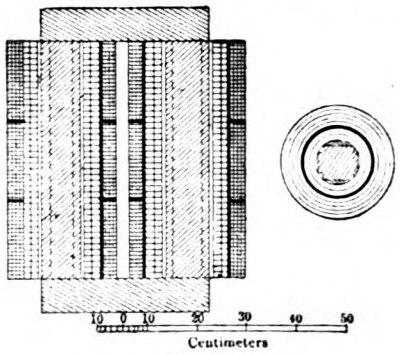

Fig. 9.

cap city. The efficiency curve and that of the total losses are shown as a function of the output in Figs. 10 and 11 respectively. The dotted lines represent the efficiency of and losses in a trans-

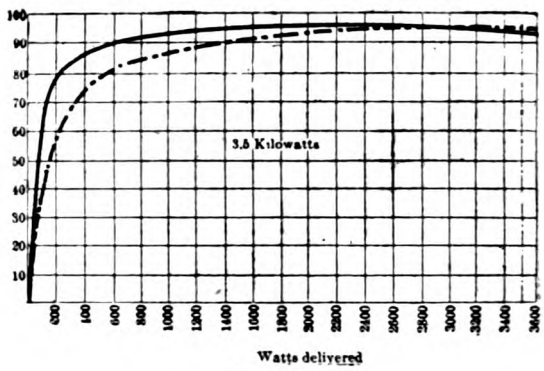

Fig. 10.

former of similar size designed on the old lines, namely, with only 2 per cent. copper loss against 4 per cent. iron losses.

Fig. 12 represents a bigger transformer, namely, one for 20 kilo-

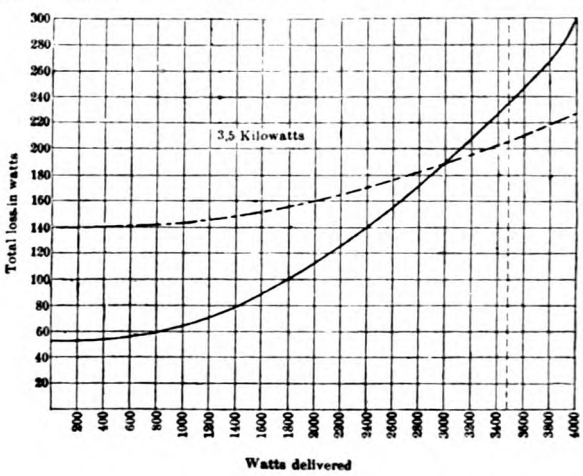

Fig. 11.

watts, transforming down from 5,000 volts to 100 volts, at 80 alternations. Both low-pressure coils have 76 turns of rectangular wires, 120 sq. mm. cross section; while the high-pressure coils are

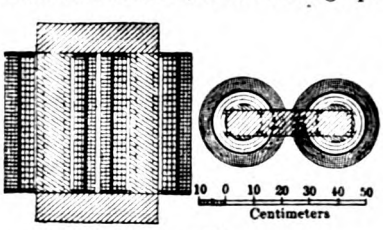

Fig. 12.

wound with 3,760 turns of 2 mm. wire, 3·14 sq. mm. cross section. The total resistances are: low pressure, 0·0121 ohm; high pressure, 34 ohms, when warm. The copper loss at full capacity is, therefore, about 5 per cent. The total weight of copper, in round

Digitized by Google

figures, is 330 kilogrammes. From the iron sectional area of 110 sq. mm. it follows from the dimensions given in Fig. 12 that there is a weight of iron of about 160 kilogrammes. The magnetic density in this instance is also about 4,000. Assuming here, again, the same moderately good iron, we get a no-load loss of about 160 watts, or only 0·8 per cent. of the total capacity. Figs. 13 and 14 give the efficiency and losses curves respectively. Here, again, the curves for a typical transformer are given for the sake of comparison, the loss of pressure being assumed as 2 per cent. and the energy required at no load also at 2 per cent. We see in both sizes

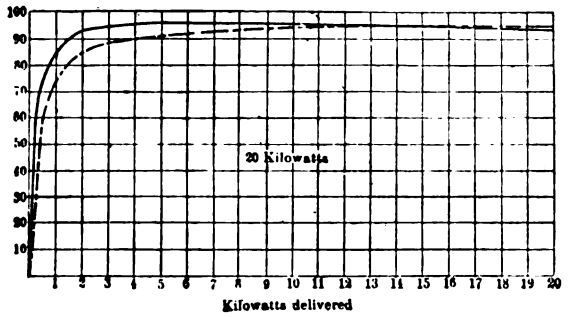

FIG. 13.

that the new type of transformer has less efficiency at maximum load than the old type. We will now deduce and compare the losses and efficiencies from the loss curves in Figs. 11 and 14, and

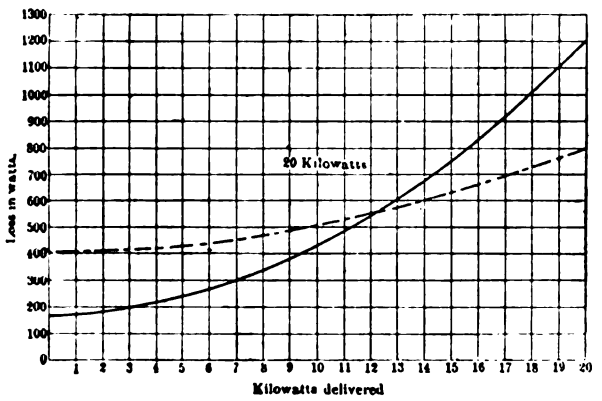

FIG. 14.

from all-day consumption curves of Fig. 6. Taking 1,000 amperes × 100 volts = 100 kilowatts, as winter maximum, we get the results shown in Table A.

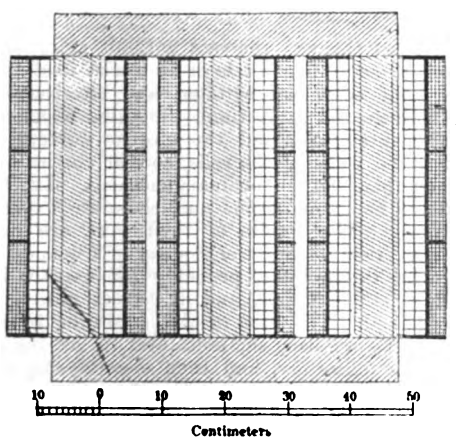

FIG. 15.

We see from this table not only the great superiority of the new method of designing transformers, but also that even when using them under the most unfavourable conditions, such as obtain when failing to cut out surplus transformers in the summer time, and when there are no motors during the day, the losses are still only of minimum amount, and there can be no question of their efficiency.

"Drehstrom" transformers, the latest arrangement of which I have shown in Fig. 15, are based upon the same principles as alternate-current transformers; and what has been said applies equally to both. I trust I have proved the very universal notion that transformer installations cannot pay—on account particularly of enormous loss during the daytime—to be without foundation, and with it the last prejudices against the introduction of the "Drehstrom" for long-distance transmission and distribution must disappear.

Table A.

—	Using transformers.			
	3·5 kilowatts.		20 kilowatts.	
WINTER.	Old type.	New type.	Old type.	New type.
Output of transformer in kilowatt-hours	573·0	573·0	573·0	573·0
Loss in kilowatt-hours ...	103·5	54·7	55·4	38·2
All day efficiency	84·7%	91·25%	91·2%	93·7%
SUMMER.				
Output of transformer in kilowatt-hours	186·0	186·0	186·0	186·0
Loss in kilowatt-hours ...	96·6	36·3	48·6	20·7
All day efficiency	65·8%	83·8%	79·2%	90·0%

THE PROBLEMS OF COMMERCIAL ELECTROLYSIS.*

BY J. SWINBURNE.

(Concluded from page 369.)

Electro-Metallurgy of Copper.

Electrolysis may be employed either in connection with the extraction of the copper from its ores, or in refining copper, especially when there is silver alone, or with gold in addition, to be extracted.

In the first case—that of extraction of copper from pyrites—the ore may be converted into matt, and the matt can be cast into anodes, or the ore may be acted on by oxidising solutions produced by electrolysis, or the two processes may be combined.

In the first method the matt is cast into anodes, which are treated in baths of copper sulphate with copper cathodes. The sulphides are attacked, sulphate of copper is formed, sulphur and impurities being left on the anode. The copper is deposited, and iron remains in solution. The chief difficulties in connection with this process are that the anodes are brittle and troublesome, and are often eaten away unevenly, and the solution becomes richer and richer in iron salts. In addition to this, it is stated that the circulation of the iron salts must be avoided, otherwise ferric sulphate will be produced at the anode and reduced at the cathode; and this process will go on wasting power over resistance. Some sort of diaphragm is therefore necessary.

It must be pointed out that sulphuric acid can be made from the sulphur dioxide given off in the first roasting of the ores, or from the surplus ferrous sulphate. The ore can be roasted so as to have a good deal of soluble oxide of copper, which can be dissolved in the acid and treated electrically. Merely working with anodes is an incomplete process; it is better to combine it with extraction by lixiviation. The solution, after being in contact with the anode, so as to contain ferric sulphate, is led to the ore. The ferric sulphate is reduced, and the copper and iron are said to be dissolved, and if there is oxide of copper it is taken up by sulphuric acid. This solution is led to the cathodes, where the copper is thrown down, and is then passed to the anodes, where the iron salt is oxidised. The various impurities and the precious metals are left with the sulphur of the anode. The sulphur is burned into sulphur dioxide, which goes to the chamber, and the silver, with the gold, if there is any, is extracted. The sulphate of iron can be burned into sulphur dioxide, and the iron oxide sold as Venetian red. This is, in rough outline, the Marchese process. It may seem strange to those unacquainted with industrial chemistry that if you want to extract copper you should also become involved in making sulphuric acid and red paint; but in chemical works by-products must be utilised, so that often making one thing involves the production of a number of other substances which have, at first sight, nothing to do with it. Messrs. Siemens and Halske avoid the necessity of making anodes of matt by employing carbon. The ferrous sulphate is thus oxidised into the ferric salt, and this is used to lixiviate the crushed and roasted ore. The solution is then led to the cathodes first to take out the copper, then to the anode to oxidise it, and so on.

In the Höpfner process chloride of copper is used instead of sulphate. The action is stated to be as follows:—Cupric chloride is formed at the anodes; this is led to the matt, where it attacks the copper sulphide, forming cuprous chloride and sulphur; and it is also said to dissolve the silver as well as the copper, which, if possible, would be a drawback. I do not know why the chloride

* This Paper will be discussed at the Institution of Electrical Engineers at one of the first meetings after the recess.

Digitized by Google

should be preferred to the sulphate; and no information is given as to what is done with the sulphur in the ore, and with the excess of ferrous chloride that must be produced.

The Marchese and Siemens and Halske processes are in commercial operation, and the electric extraction of copper is already a growing industry. The electromotive force necessary for this process is less than a volt; so that, assuming coal to be used, as in the estimate at the beginning of this Paper, the electrical cost is 14s. 5d. per ton for the extraction of copper. I cannot give the whole cost, as that involves so many considerations. This figure will give copper smelters some idea of the saving of replacing the ordinary refining process by electrolysis.

In dealing with such a valuable substance as copper the time element must not be neglected. The interest on the money locked up in the copper under treatment may be a very serious item. This is an objection of some weight in the case of matt anodes, which take some time to dissolve. The whole of the copper turned out is not obtained from the anodes; but, taken all round, it may not be far wrong to assume that the copper takes about three months to pass through the works where matt anodes are employed. If the output is, say, 1,000 tons a month, the copper represents a capital of some £150,000, and the interest increases the cost of refining some 12s. a ton.

Electrolysis may also be employed for refining crude copper. In this case the process is simplicity itself. The crude copper is made into anodes, and thin plates of fine copper are used as cathodes, the electrolyte being sulphate of copper. Pure copper is deposited on the cathodes, and the impurities, and the silver and gold, are left in the mud, and the precious metals are extracted in the ordinary way. It is usual to employ cast anodes, and arrange the plates in each vat in parallel, the vats themselves being coupled in series. This arrangement is clumsy, and should be modified. I have had an opportunity of examining the large copper refinery at the Bridgeport Copper Works, and it may be well to describe the arrangement employed there. As the books were examined by Mr. J. H. Hays at the same time, I am also able to give you the actual cost of the process, without having too roseate a hue imparted by an enthusiastic inventor. The refinery is arranged and worked in accordance with the patents of Mr. E. S. Hayden. The departures from ordinary practice are made with the view of reducing the amount of copper under treatment, and of keeping down the cost of labour.

The anodes, instead of being thick cast copper, are sheets of thin rolled metal. The cost of rolling is small, and the plates used can thus be made thin, and dissolved very uniformly. Each vat contains a number of plates arranged vertically and across the vat. At one end a thin plate is supplied as a cathode. The first plate is made the anode, and copper is eaten off one side of each plate, and deposited on the plate next to it. The result is that each vat acts as a number of small vats arranged in series, and requires only two electrical connections. The whole question of large leads and connections is thus solved. There is almost no waste through partly consumed anodes, as the whole plate is eaten away evenly. The process is carried on until the whole of the anodes are eaten, and their place taken by the pure deposited copper. The plates are hosed and removed, and the slime is treated to recover the silver and gold. The product is the highest grade of copper in the market, and fetches £6. 10s. a ton above "tough cake," or £4. 10s. above "best selected." Silver and gold are completely separated without loss, and as 35oz. of silver and ½oz. gold per ton are allowed as tare, any copper containing more than that yields £8 per ton in bullion. Argentiferous copper thus yields at least £14. 10s., leaving the gross profit of £12. 10s. at present rates. I have here taken the cost of refining at £2 per ton. The actual cost of refining copper depends on the output of the works and the cost of labour. In Bridgeport it came out just over £2 a ton. With modern dynamos, and reasonably good engines and labour at English prices, the cost would be a good deal less, say 20s. per ton. The use of thin plates as anodes also reduces the capital investment in copper, which, as already pointed out, may be enormous, and thus lessens the margin to be allowed for fixed charges.

The Elmore process is too well known to require a full description. The copper is deposited on a revolving mandrel and burnished by a travelling agate burnisher. By this means copper tubes of great strength are made, and by cutting the tubes sheets are produced. Narrow strips can also be made, and these can be drawn down into high-grade copper wire. A number of thin sheets can be made by depositing several separate coatings one over the other on the mandrel. The sheets separate when the tube is slit lengthways.

Writers of books on political economy are fond of saying that the chaffering of the market makes people manufacture in the cheapest way, and that the cheapest and best goods displace dearer and inferior qualities. They forget the interference of custom, ignorance, and prejudice. If a new process is brought out, it takes ages before it is taken up abroad, and still longer before Englishmen will touch it. Here we have a process of refining copper at a gross cost of £1 or £2 a ton, with a gross profit of £13 or so; and yet copper refiners continue their barbarous methods. The first manufacturers to take up copper refining by electrolysis on really modern principles have a chance of making fortunes before the market is disturbed.

Antimony.

Little has been done in the way of treating antimony ores electrolytically. Dr. W. Borchers proposes to use the solution of sulphide in sodium sulphide as an electrolyte, and to deal with the ores. The specimens of antimony ore that I have examined have been perfect insulators, so that regulus of antimony cannot be used as an anode. There will be an accumulation of sulphur in the bath, and it will probably insulate the anode. It is also difficult to say what material could be employed as anode in such a solution. Carbon would be attacked, and platinum would be too expensive, and other metals would be converted into sulphides. As the reduction of antimony by iron, for example, is comparatively easy, there does not seem to be much opening for the electrolytic treatment in dealing with its ores.

Recovery of Tin from Scrap Tin.

This, of course, can be readily effected by electrolysis. The scraps can be made the anode in an alkaline solution, in which iron is not attacked. Though such a method removes all the tin from the surface, it may leave some alloyed with the iron, as no doubt some tin sinks into the iron during dipping.

Electrolysis has also been employed to assist in cleaning plates before dipping. I do not see how it can be of much service here, however. I have examined one of the processes, and it was said to be working very successfully, but I found the brushes had been accidentally left off the commutator.

Electrical Tanning.

Electrical tanning, though it depends on electrolysis, differs materially from all the processes already described in not depending on the isolation of radicles at the electrodes. Ordinary tanning is a very slow process, because it takes a long time for the tannin to diffuse into leather properly. If this substance is an electrolyte, it has a very complex molecule, and therefore diffuses very slowly. The outside of a thick piece of leather also becomes tanned, and to some extent protects the rest from the diffusion of more tannin We may get an idea of what I suggest is the action in electrical tanning by regarding a hide as being made up of cells in groups, with interstices among the groups. If the skin is merely left in tan liquor, it takes months for the liquor to penetrate even into the interstices. It has then to diffuse through the walls of the cells. This is necessarily a very slow process, when it is remembered that the gelatine uses up the tannin as it comes in. Mechanical agitation has been tried, but it does not accelerate the process much. It is probable that agitation helps the liquor into the interstices, but of course it cannot help it into the insides of the cells, or, in fact, into those parts of the leather which are accessible by diffusion alone. The agitation can thus only perform the first part of the process—that is, getting the liquor into the pores that are open to it.

Passing electricity through the vats without agitation has also been tried, but it, again, is of little or no use by itself.

If, however, the skins are agitated and electricity is passed through the bath at the same time, the agitation circulates the liquid into the interstices, and the electric current sends the tannin through the walls of the cells, so that the leather is made infinitely faster than by the ordinary methods. Dr. Rideal and Mr. Trotter have made numerous and elaborate experiments on electrical tanning. The results of their work are given in the exhaustive Paper read before the Society of Chemical Industry. I brought forward this as being probably the explanation during the discussion on their Paper, and it agrees entirely with the results they obtained. The best results, according to this theory, would be secured by agitating the hides first to get the liquor into all the interstices uniformly, and then electrolysing to get the tannin into the skin itself; then agitating to refresh the solution in the pores, and then electrolysing, and so on. Messrs. Rideal and Trotter showed that this method does, in practice, give the best results. Leather made in this way also has a better chance of being uniform, because the outside is not acted on perceptibly quicker than the inside.

Tanning by agitation and electrolysis combined seems to have been invented by Messrs. Worms and Balé, and their process has been worked successfully for some time past in France, and in England by the British Tanning Company. Mr. Groth has developed a modification, and is also making leather by this process. Groth's appears rather better than ordinary leather, being more uniform in texture, and giving better results when tested for tensile strength. It was shown at the Crystal Palace Exhibition this year.

Ozone.

Now that induction coils in the shape of transformers have become commercial, there is every reason to expect that ozone will

Digitized by Google

be made industrially. Mr. Fahrig has already been making ozone commercially in this country. He employs an alternate current which works a transformer which gives a high electromotive force. Air is first drawn through an apparatus which is supposed to separate the nitrogen by diffusion. As nitrogen and oxygen have nearly the same densities, it is hardly likely that much nitrogen is separated. The air is then led through the ozonisers. These consist of piles of corrugated metal plates with sheets of celluloid between them. They are alternately positive and negative, being connected to the high-pressure side of the transformer. There is thus an alternating discharge from the corrugated electrodes to the celluloid sheets, so that the air is ozonised on passing through.

Messrs. Siemens and Halske employ ozonisers of the more usual form. Two concentric glass tubes are used. One electrode is inside the inner, and the other is outside the outer tube. High-pressure transformers are of course employed, and the air, or oxygen, is partly converted into ozone on its way there. Very little is known about the electrolysis of gases, if such an expression is admissible. The so-called silent discharge seems to work best, but the whole subject now demands quantitive investigation. The use of glass must involve low efficiency, as glass possesses the property of dielectric hysteresis in a high degree. We also want to know the current-density and freqnency which give the best results. The arc, and, in fact, many forms of electric discharge, produce traces of nitrogen compounds. It is worth pointing out that if under any commercial conditions nitrogen compounds can be produced from air, there would be an unlimited demand. A works situated on a waterfall would have its power and material provided, and the only cost of production would be the interest on plant, and the wages of a man or two to look after the dynamos.

It has been said that chlorine acted on by the electric discharge is affected in the same way as oxygen. In the first place, chlorine is already quite a strong enough oxidant; and in the second, it is difficult to see how chlorine can form an allotropic modification.

Miscellaneous Processes.

Under this head I have classed a few electrolytic processes whose theory is obscure, and about whose practical success there may be some doubt.

Mr. Webster has brought out an electrolytic sewage process. The effluent has electricity passed through it, and this is said to separate the solid material completely, and to kill all germs. Of course, when any sewage containing salt is electrolysed it produces chlorine or hypochlorites, and these would act on organic matter. Hermite, for instance, has applied his process to the disinfection of ships. This does not seem to be the basis of Webster's process, however, and there seems uncertainty as to what the action is supposed to be, and why the solid particles should be influenced by the current.

The next process is ageing wine and spirits by means of the electric current. Whether there is really anything in this I do not know. Various inventors have brought out methods of ageing liquors by electrolysis. There is uncertainty as to whether the result is produced, and as to how it is produced. Various deleterious alcohols might be oxidised into ethers; but it is strange that electricity should select just those that give a taste which is unpleasant to the human palate. Mr. Turell uses a direct, while M. de Meritens employs an alternating, current.

The sterilisation of milk by electrolysis is another process which is somewhat obscure.

The Electric Furnace.

The idea of using the heat of the arc for producing high temperatures for such purposes as melting iridium is about half a century old. Recently, however, we have had the Cowles furnace, used especially for the reduction of alumina. Properly speaking, this does not come within the scope of this Paper, as there is no reason to suppose that electrolysis has anything to do with the reduction of the oxide. By pouring the power from a large dynamo into a carbon resistance, closed in so that the heat cannot readily escape, a very high temperature is produced. Alumina is then reduced by the hot carbon. It may be taken that at lower temperatures, such as those produced by ordinary furnaces, the affinity of aluminium for oxygen is greater than that of carbon, and that at the higher temperature the reverse is the case. It is not impossible, however, that the carbon in an ordinary furnace is inactive merely because it cannot get into good contact with solid alumina, and that in the Cowles furnace the alumina melts. In any case, there is no reason to suppose there is any electrolytic action going on.

The Cowles furnace is applicable to all processes which demand very high temperatures, such as the reduction of oxides of aluminium, magnesium, calcium, barium, strontium, silicon, chromium, boron, tungsten, and manganese. Of course many of these metals are not at present in demand; but then, it must be remembered, that may be because there has, until now, been no way of making them reasonably cheap. Many, if not all, of these metals have been already obtained by the Cowles process.

It is a question of economy whether the Cowles furnace should not be employed in many other reduction processes which do not require such high temperatures. The furnace is efficient, as the heat is applied where it is wanted, and little is wasted by radiation or convection. We thus have to compare an ordinary furnace in which the heat is applied badly, and a great deal is wasted because the gases go off at a very high temperature, with a system which begins with an efficient furnace working a very inefficient heat engine and an efficient electrical machine. The electrical furnace will doubtless soon be applied in many cases, especially those which ordinarily involve inefficient furnaces, and retorts which break down quickly or leak.

The manufacture of phosphorus is a good example. On paper the process is simple. Bone ash, or tricalcic phosphate, is not reduced by carbon at ordinary furnace temperatures, so it is treated with sulphuric acid, and converted into monocalcic, or superphosphate. Making this involves making sulphuric acid, or buying it. Acid phosphate is then heated in retorts with carbon, and two-thirds of the phosphorus is obtainable theoretically. If sand is used it acts as a strong acid—or, rather, anhydride—at high temperatures, and all the phosphorus should be obtainable. The retorts, of course, give rise to trouble and expense. Messrs. Readman, Parker, and Robinson, by employing the electric furnace, can deal with mineral phosphates, and require no sulphuric acid. I do not know whether carbon at the temperature attained in the electric furnace will reduce calcium phosphate to calcium and phosphorus, or whether calcium phosphide is formed. With sand, of course, calcium silicate is formed. One might expect that this would be reduced to calcium and silicon, in which case it would be reasonable to suppose that the operation cou'd be carried on without silica. It has been said that some oxides which can be reduced by very hot carbon when dealt with separately, can form compounds that cannot be reduced if one oxide is strongly acid in comparison with the other. If that is the case, though the lime and silica might be reducible separately, the combination of the two, calcium silicate, might be irreducible. Whether calcium silicate is reducible or not, silica must, of course, be employed if the phosphate would otherwise be converted into phosphide.

It would be well to see what other reduction processes could be dealt with economically by the Cowles furnace. Doubtless there are many, and Messrs. Parker and Robinson are sure to explore the field pretty thoroughly.

Conclusion.

A very few of the possible applications of electrolysis have been described in the foregoing Paper, and the labours of many workers have been passed without mention. This was unavoidable. There is also another difficulty in writing such a Paper as this: I have not worked at all the processes myself, and have had to rely on published accounts in many cases. Out of every hundred new inventions in electro-metallurgy, ninety are impossible chemically or electrically. If I have ruthlessly cut out a possible or admitted an impossible process, I must ask pardon on account of the impossibility of trying all the processes myself, even experimentally, and must plead that I have been as sceptical as possible.

There are other directions in which electrolysis may play an important part. The improvement of the manufacture of white lead deserves the most careful attention. The Dutch process is unhealthy, costly, and barbarous. The electrolytic manufacture of analine dyes has received considerable attention. Dr. Goppelsroeder has done a good deal of work in this direction, and samples of silks dyed by electrolytically prepared colours were shown both in the Paris and Frankfort Electrical Exhibitions. The extraction of gold from sea water, which is said to contain minute quantities, need hardly be treated seriously. Even if it were possible, such a process would be of no use. All improved processes for obtaining precious metals merely enrich some at the expense of others, and reduce the value of the metals. Obtaining gold more easily would be no good to the community unless it became cheap enough to be used commercially.

THE LANE FOX APPEAL.

Not content with having established beyond doubt, in the case which was tried in March last by Mr. Justice A. L. SMITH, that he was one of the pioneers of electric lighting, if not the veritable discoverer of the principle of parallel distribution at constant pressure, Mr. LANE FOX has endeavoured to get this view confirmed by the Court of Appeal, and took the opportunity of urging the corollary which the Chancery Judge failed to appreciate, namely, that he was entitled to royalties from all those who use secondary batteries in conjunction with dynamos for running glow lamps. And now, after some five weeks' deliberation, the Court of Appeal has confirmed byth the legal decision and the pious opinion of the Court below. Mr. LANE FOX, says Lord Justice LINDLEY, undoubtedly made a great step in advance; he was a pioneer, and showed the road to be followed, but he did not give the traveller the information necessary to enable him to travel on it; and, in consequence, Mr. LANE FOX was not considered legally entitled to levy royalties from those to whom he showed the way in this insufficient manner.

In our comments upon the judgment of Mr. Justice A. L. SMITH we observed that the trial had not shaken Mr. LANE FOX's claim to the discovery of the practicability of parallel distribution at constant pressure, but that, on the contrary, it had established his position on surer ground, and in spite of rather unworthy efforts (which were repeated during the appeal, but with no very great success), to show, or rather to assert, that Mr. LANE FOX had exercised no invention, but had taken well-known things, and had merely attempted, and that unsuccessfully, to accomplish something which would not in

Digitized by Google

any event have been of any use. These very assertions elicited from Lord Justice KAY the very clear and just dictum that the man who first applied secondary batteries to dynamos and lamps was a great inventor. We have always held that the attempts to detract from Mr. LANE FOX'S reputation as the enunciator of the principle of parallel distribution for incandescent lighting have failed. But we admit at once, as we have done on a former occasion in this connection, that a principle cannot be patented; and the question for the Appeal Court was, as it had been for the Court below, "Is the patent No. 3,988 of 1878, as twice amended, valid?" Judgment has now gone against Mr. LANE FOX in both Courts on the ground of disconformity. Regulation and a regulator were features of the patent; and the point at issue was whether the regulator could be abandoned, and the regulation tacked on as an inherent property of something else? to wit, a secondary battery which was left in the amended specification. On this head the judgment, which we give in another column, states most unequivocally that no such intermutation can be allowed.

The second point in Mr. Justice A. L. SMITH'S judgment was that the system described in the specification was impracticable, and that an intelligent workman could not successfully carry out the invention without experiment and further invention. It is idle to argue, as was done in both the trial and the appeal, that the description was incomplete. What patent specification seems to be complete when it is a dozen years old? Common sense is not all that is to be applied to a patent case; but according to our system of law the decisions in previous cases are the main guide. Take one, for example. EDISON *v.* HOLLAND was decided by the kneading of a mess of tar putty, which was rolled out into a filament; not by the instructions in the patent, but by the marvellous ingenuity and perseverance of highly-skilled experts. And after this had been done, lamps were made, which glimmered for two to sixty hours; and this was held, not by the Judge in the first instance, but by the Court of Appeal, to be a "practicable process." It is time, therefore, that laymen should prepare themselves to look at patents through legal glasses. Then, as to this everlasting intelligent workman. True, he is the man of the hour; he dictates our laws, and is ready to do anything but pay taxes and work. He, too, is the arbiter of the practicability of patent specifications. Patent a corkscrew, and you must so describe its construction that the intelligent workman may, if he be so inclined, fashion one by the light of the information supplied. But the LANE FOX patent is really for the planning and laying out, and for the designing and the construction of a central station and a network of mains. Is our intelligent workman to do all this? We have followed the evidence and argument in both trial and appeal with considerable attention, and are still of opinion that so far as the battery is concerned, there seems to be no reason why a set of large simple inexpensive accumulators of the Planté type with ample conducting surface, that is area of plate, and not overburdened with active material, should not work very serviceably between, say, 4 to 5 volts up and down. In our comments on the trial in the Court of Chancery, we said that the weakest point in the plaintiff's case seemed to have been the liability of secondary batteries to sulphation unless occasionally charged up to 2·5 volts per cell, and we thought that the necessity for their thorough charging ought to have been frankly admitted. But since that date we have heard more of the much despised Planté. The great discovery of Mr. DRAKE was applicable primarily to pasted cells, and to a less degree to thoroughly well-formed Plantés, formed in fact for real storage purposes. But the simple Planté has a much more hardy constitution, and sound evidence to this effect could, we believe, have been brought forward by Mr. LANE FOX. Ordinary Planté cells would have been valuable adjuncts to the engines and dynamos not only of 1878 but of 1885. That they would hardly be worth having to-day is another matter. But the Appeal Judges here again concur with Mr. Justice A. L. SMITH. Without the ingenious switches and dodges added since 1878, they hold that it would have been altogether out of the question to have applied Planté batteries to a central station network.

The appeal was usually interesting, and at times amusing. Mr. LANE FOX was assisted by his solicitor, and for the greater part of the case by a single expert; while the opposing counsel was supported by one or two barristers, an invaluable expert continually at his elbow, and sometimes half-a-dozen others who looked in to see how the case was going. Lord Justice KAY, from the very first half-hour, took a leading part, feeling, no doubt, that he had not gone through EDISON *v.* HOLLAND for nothing, and being less alarmed, perhaps, than the learned Judge before whom this tangle was first unfolded, he took a broader view of such questions as the alleged difference between regulating and keeping the pressure constant. One of the first remarkable points in the case was the curious extract from Mr. KING'S evidence, which was quoted in Mr. Justice A. L. SMITH'S judgment. Extorted as it was under severe cross-examination about an exceedingly complicated experiment which appeared to have very little to do with Mr. LANE FOX'S invention, and which the counsel certainly failed to understand, the assertion that there would be more variation in the mains *with* batteries than without them was one which required a good deal of explanation, and was, we think, quoted by Mr. Justice A. L. SMITH quite apart from its very involved context. Although Mr. LANE FOX'S view that it was a deliberate misstatement of fact was too strong, it was one of those assertions which the scientific witness, alas, too often makes. Not without reason Mr. LANE FOX declined to take the so-called Ayrton curve as a basis of argument; and no better reason could he have brought forward than the one which he gave in the closing words of his reply. The fact did not transpire during the trial on the appeal that the charge and discharge curve of a pure Planté is altogether different from that of a pasted plate, or even, probably, from that of a heavily-formed lead plate such as the Crompton-Howell; and further, that the "plateau" is flatter, and therefore much more favourable to Mr. LANE FOX'S contentions. A point on which we have to differ with Mr. LANE FOX is his analogy of the compression of gas into an iron bottle. When he first introduced this it was, perhaps, legitimately used; but he brought it up on two subsequent occasions during the appeal to attempt to show that, as a bottle of gas can always be made to hold more if the pressure be increased, so a secondary battery can never be said to be full—a most misleading idea. The distinction which Mr. LANE FOX drew between large conducting surface and large active surface was important; but he was not really entitled to introduce it, as it was fresh evidence, and Mr. WALLACE was fully justified in rejecting it on these grounds, as he did when opening his reply, together with the other new and rather weak argument that 110-volt lamps might be used if it were necessary to go to 110 volts in charging.

In the end, if the plaintiff has suffered in pocket, he has at any rate vindicated his reputation as an electrical engineering pioneer. The Court of Appeal, in common with nine-tenths of our present-day electricians, may not, perhaps, have made sufficient distinction between the

Digitized by Google

modern and the plain Planté storage cell, and their notion as to the amount of information which should be given in a patent specification may seem rather excessive; but that there was a decided disconformity between the provisional and final specifications there can be but little doubt, and this alone settled the question of validity. The situation is, we think, succinctly summed up by Lord Justice LINDLEY. "An invention," he remarks, "may be useful as indicating the direction in which further progress is to be expected, and yet that same invention may be useless for any other purpose, useless, that is, as an invention, without further developments which have not occurred to the patentee."

THE BRITISH ASSOCIATION AT EDINBURGH.

THURSDAY.

The proceedings of Section A were opened on Thursday last week in Edinburgh by a most interesting and suggestive address by Prof. Schuster, an abstract of which will be found in another column. Not a few members missed the pleasure of hearing it through one of those careless blunders of organisation which detract so largely from the usefulness of the Association. It was announced on the general programme that the Sectional Meetings would begin at 11 o'clock; but Section A assembled at 10, notice of the change having been made on a board in a remote corner of the Parliament Hall, which was arranged as a reception room. About a hundred and fifty members were present in Prof. Tait's lecture room. The remainder of the day was spent on sundry reports on meteorological and kindred matters, several Papers announced on the programme being postponed.

In Section G, Prof. Unwin delivered an address, of which we also print an abstract this week. This was followed by a Paper on the Chicago Exhibition, after which Prof. Forbes gave a sketch of his scheme for the electric lighting of Edinburgh. This was the only Electrical Paper in this Section on Thursday.

FRIDAY.

Prof. H. E. J. G. du Bois, in Section A, read a Paper on "Magnetic Circuits," dealing with effects of leakage. Dr. Dawson Turner followed with an experiment which failed to "come off," but which was arranged afterwards in an adjoining room. He showed that the resistance of a heterogeneous or discontinuous conductor, such as metallic powder, was affected by a neighbouring disruptive discharge; but offered no theory beyond the suggestion that there was an "orientation" of the molecules. The discussion failed to elicit anything worthy to be called an explanation, and no one having anything to say about it, Prof. Forbes made some remarks on the behaviour of sulphide of silver. That this had little to do with the subject of the Paper was of small consequence at a British Association meeting; anything will do as long as it is interesting.

Prof. E. Wiedemann described some experiments of the Hertz Tesla order. He spoke excellent English, hardly once being in a difficulty for a word. He happened to use the expression "evacuated" instead of the more common "exhausted" in connection with vacuum tubes, and the word being adopted afterwards in discussion by Dr. J. T. Bottomley, it was afterwards used by Prof. von Helmholtz and others. Some of the audience had a little difficulty in understanding the meaning of "glim licht" and "dark rooms" in the vacuum tubes. The "glim licht" was obvious, and the "rooms" were "spaces." The speaker vainly endeavoured to depict these on a blackboard, with greasy and perfectly unsuitable coloured crayons which had been provided instead of coloured chalks. The exact arrangement of the tubes and inductors was rather difficult to follow, but an important point in the communication was the distinction which was drawn between conduction and absorption. When a tube fails to glow it is sometimes said to be due to non-conductivity, but Prof. Wiedemann pointed out that since the light was due to absorption of the radiation, it should more properly be said to be due to non-absorption.

Dr. J. T. Bottomley, who has used vacuum tubes without electrodes long prior to Mr. Tesla's brilliant demonstration, described experiments with a form of vacuum tube which he showed at a *conversazione* of the Royal Society more than a year ago. The connection between the pushing of an electrode into the internal tube and the experiments of Prof. Wiedemann appear to consist merely of the extinction of the light in each case.

Prof. Schuster gave a clear sketch of investigations which he had made upon the conductivity which exists in a vacuum tube during a discharge through it, and the electrolytic phenomena and polarisation which accompany the passage of a current through subsidiary electrodes in such a tube.

Prof. Crookes' remarks, which followed, appeared to refer to Prof. Wiedemann's experiments rather than those of Prof. Schuster. He had nothing to say about polarisation, but something about the non-luminous condition of vacuum tubes without electrodes. The fact that such tubes assume a passive state is interesting, but no explanation was forthcoming. Dr. Dawson Turner had used the expression "orientation" in connection with the passive state of his metal powders, though hardly intending that it afforded any explanation; but Prof. Crookes on making a suggestion about the vacuum tubes, used another five-syllabled word—dissociation—to "account for" the phenomena. Some phenomena might be "accounted for" to some audiences by the use of a single well-chosen six or seven syllabled word. But one must not grumble at lack of completeness or method in connection with Sectional Meeetings of the British Association; and no one who was present could possibly have felt that the privilege of seeing and hearing Prof. von Helmholtz was lessened by the fact that the discursive nature of the discussion was extended by his remarks, which had nothing more in common with the business of the meeting than that they at first related to a vacuum tube, and as this one contained mercury, to other tubes containing mercury. Had he continued to discuss the properties of mercury even without glass tubes at all, no one could have resented it. Before Prof. von Helmholtz rose, however, two other foreign members made a few remarks. The name of one neither the secretaries nor chairman made any endeavour to divulge; the other was Prof. Arrhenius, who was well received by the meeting as one of those distinguished foreign visitors whom to see and hear is an attraction which no mismanagement can spoil,

Prof. von Helmholtz, was, if we may be allowed to say so, one of the principal attractions at the meetings of Section A. With an excellent command of English idiom and pronunciation, he made a few introductory remarks about electrolysis; he passed to the adherent stratum of air in vacuum tubes, and then to an extremely interesting explanation of certain effects by the contact difference between glass and mercury. Returning to the air stratum he surprised many of the audience with the fact that this, though not exceeding $\frac{1}{2000}$ of a wave length of light in thickness, was sufficient to introduce an error in the use of a column of mercury as a standard of resistance.

Lord Kelvin commented on Prof. von Helmholtz's remarks on contact potential of glass and mercury, and drew attention to the resuscitation of the older experiments, which have been neither interpreted or appreciated. We alluded only a short time ago to the return to electrostatics; and this revival has now reached a point at which, when prime conductors are again mentioned, it seems unwise to speak disrespectfully about the "head of hair."

Lord Kelvin followed with a communication upon a dynamical problem which is beyond our province to dwell upon at length. He has been engaged upon calculations of a most extensive and elaborate nature for about a year, and while he only briefly touched upon the results, he said enough to show that these are of great interest, not only mechanically, but in their application to the kinetic theory of gas and Maxwell's theory of the distribution of energy. As we have not alluded to this Paper in our report of the proceedings, we will give a brief outline of the contents. If a particle is free to roll in a smooth curved trough, it can either be projected in a straight line, rolling along the bottom of the trough, or it may be dropped from the edge, and, running down one side, it will by its momentum run up the other, and, returning, oscillate

Digitized by Google

in a plane perpendicular to the length of the trough. If it be projected in a general direction, it will follow a path compounded of these two motions. The motion in the length of the trough is not affected at all by the oscillatory motion, and *vice versâ*. If, however, the trough is not of constant curvature, one part being flatter and another deeper, an exceedingly interesting result follows. The irregularity will give rise to instability, and the particle will oscillate more and more widely and would soon fly over the edge of the trough. The edges might be curved inwards to retain it, or it might be covered in, forming, in fact, a tube. Exactly the same result will take place if, instead of irregular curvature, the tube were rough. There is no limit to the instability of the oscillations, and if enough energy is imparted, the particle may rise to the top of the tube, and may even return. Another arrangement of the problem is a horizontal plane, below which a number of magnets are placed at intervals; an iron ball projected along the plane in a direction slightly inclined to the row of magnets will be diverted by the magnets as it passes them, causing it to oscillate more and more widely. This ball of iron, said Lord Kelvin, would, of course, have no magnetic friction or hysteresis to trouble pure mathematicians. Another form is a succession of convex lenses. If a ray is sent through them it will zigzag through them, and if they are not each closer together than one-quarter of their focal length, it will become unstable and escape. Lord Kelvin, who was in his best form, described the problem in a most graphic manner, and, attended by three trembling assistants armed with sponge, rag, and chalk, covered a blackboard with curves showing the laws of stable and of unstable periodic motion. The board, being arranged in three vertical sliding portions, was shifted by his assistants, one portion at a time, until it was covered with a bewildering diagram of curves interspersed with i's, signifying impossible solutions. So far from having been exhausted by his discourse, Lord Kelvin proceeded to demonstrate some simple cases of the problem by a model consisting of a crank and jigging arrangement from which a small wire pendulum was suspended. The crank being turned, the pendulum soon began to oscillate until it turned completely over and finally smashed. This was replaced by a longer pendulum of string, which, too, was set in oscillation by the vertical motion, the greatest swing being produced when the period of the vertical motion was twice that of the natural period of the pendulum. A faster motion jerked the ball, the force being greater than that of gravity, and had the experiment been continued, the ivory ball would probably have made a disruptive excursion into the middle of an intensely interested audience.

Prof. Osborne Reynolds alluded to experiments at Owens College, Manchester, on the stability of structures and the periodic conditions of a rapidly revolving shaft. Illustrating the problem by the handling of a long pointer, he suggested another problem of periodic stability to Lord Kelvin, who seized the rod and endeavoured to balance it on the tip of his finger, at the same time, giving it a brisk up-and-down motion, saying that this, if properly executed, would impart stability to the rod. Prof. von Helmholtz alluded to the production of waves on the surface of water by means of air currents, and showed by means of curves on the blackboard how, after a certain condition is exceeded, the crest must burst into a breaker.

About 120, and at one time nearly 150, members were present at this very interesting part of the meeting; but the subject of the next Paper, the ever-to-be-discussed and never-ending "Efficiency of Transformers," caused something like a 50 per cent. drop in the attendance. Prof. Ayrton communicated the results of Dr. Sumpner's method of measurement, and Dr. Sumpner gave additional information, illustrating the subject by curves of losses under different conditions.

Prof. Reinold then read a Paper on "The Electrical Conductivity of Thin Films," the audience having now become decimated; and at about 1:30 p.m., before an audience of about 22, Mr. Magnus Maclean discussed some experiments with an Induction Coil; and the meeting was brought to a conclusion by a Paper from Mr. J. Gray on "The Theory of a Perfect Influence Machine."

Simultaneously with the most important Papers in Section A on Friday, a Paper was read by Mr. A. Siemens on "The Electric Locomotives on the City and South London Railway," which will be found in another column. This was followed by a brief discussion, after which a Paper by Messrs. Purdon and Walters on "A Stream Water-motor" was read. The apparatus consists of a number of blades mounted on a chain like the buckets of a dredger, and set in motion by a flowing stream. The authors claimed an efficiency of 25 per cent.; but in the discussion Prof. Unwin pointed out the uselessness of the expression "efficiency" in such a case. It was only a question as to how much horse-power could be got out of it Prof. Blyth then described and exhibited models of windmills for generating electric light to an audience of 30, of whom eight were ladies.

Saturday.

The proceedings in Section A on Saturday commenced with a Paper by Mr. Magnus Maclean on "The Sources of Heat in the Galvanic Battery;" and Dr. Peddie gave an account of measurements of the electric conductivity of bismuth and copper in magnetic fields. Prof. Michelson described a new method of spectroscopy of considerable importance; and Mr. A. A. Campbell Swinton exhibited some enlargements of photographs of electrical discharges and several prints from negatives, on which the spark from an induction coil had produced a direct image. Mr. J. H. Gray described an instrument for drawing electrical oscillations of slow period. The apparatus, which was not very clearly explained, seemed to depend upon the action of an electromagnet excited by the oscillatory current. The curves were traced on smoked paper. Prof. von Helmholtz, whose name was alluded to in connection with the mathematical treatment of this subject, made a few remarks, and thought that the method given in the Paper could hardly be expected to give good results. He described his well-known condenser method with double contacts at known intervals of time.

A Paper on the scientific amusement known as "Inductoscript," by Rev. F. J. Smith, was read, and photographs of impressions of coins made in this way were exhibited. With Lord Kelvin's warning in view we will not disparage this experiment which has recently been brought before the Physical Society. Mr. Swinton's photographs were interesting as indicating distinct differences between positive and negative sparks, and they may some day throw light upon a difficult subject; but "inductoscript" photographs of coins seem to be little else than curiosities. Prof. Smithells showed some very interesting experiments with modifications of the Bunsen flame, which gave rise to a long and animated discussion, in which Lord Kelvin, Prof. von Helmholtz, Sir G. Stokes, and others took part, the chief question being whether the spectra of flames are due to the temperature or to chemical combination. During Prof. Michelson's Paper about 50 members were present, and about 40 remained to the end of the meeting.

Monday.

On Monday a large audience was attracted to Section A to hear the discussion on a "National Physical Laboratory;" but were somewhat disappointed. Lord Kelvin followed with two mathematical Papers. One of these was on the "Reduction of Every Problem of Two Freedoms in Conservative Dynamics to the Drawing of Geodetic Lines on a Surface of given Specific Curvature;" and he explained that the problem of drawing geodetic lines was attacked by every shop assistant who attempted to tie a parcel with string. The string should take a certain route between two points, or it might slip off. He alluded to the universal importance of the method of least action, and then went into a general problem on the motion of bodies with two degrees of freedom, illustrating the matter by swinging a door and rotating a foot-rule supposed to be attached to it. The aiming of a gun was another example of two degrees of freedom, altitude and azimuth, and the mathematical treatment of the problem appeared to prove that one can always hit the target; though the path of the projectile may, indeed, be sometimes imaginary. He described a system of kinetic triangles and admitted that certain mathematical work was the art of making easy things difficult.

Digitized by Google

Monday in Section G was supposed to be devoted to Electrical Engineering; but after the presentation of a valuable report on "Graphic Methods" by Prof. Hele Shaw, there were only two short Papers by Mr. Preece on telegraphic matters; a Paper by Mr. Kapp, in which the really interesting points relating to a set of curves are not alluded to; one on "Electrical Locomotion," by Mr. Woods; and the promise, which was not fulfilled, of a Paper on "Coal Cutting by Electric Power."

A discussion on Prof. Hele Shaw's report was allowed, although it is not customary with the British Association to permit any discussion upon reports, and resolutions thereon are altogether out of order. The audiences at the Sectional Meetings are undoubtedly of a very heterogeneous character; and it would be unwise to give a voting power to those who look in to hear a discussion between Lord Kelvin and Prof. von Helmholtz on their way to a discourse on "The Use of Narcotics by the Nicobar Islanders," having been disappointed by the non-appearance of Prof. Garner, who was to have lectured on the language of monkeys, or perhaps having been bored by "Syntheses of Butane and Pentane Tetracarboxylic Ethers." But discussions were permitted on more than one occasion this year; and after Prof. Hele Shaw read parts of the abstract of the report on "Graphic Methods," and had given a few examples of their use, one speaker urged the committee to further encourage this branch of mathematics by the issue of the further report which was suggested by Prof. Hele Shaw, and complained that there was apathy, if not prejudice, among many mathematicians against graphic methods. He said that Germany was far ahead in this, and that some graphical methods used in Germany are as unknown to English engineers as differential calculus is to the Fiji islanders. Another speaker thought that if the report could be extended, publication should be deferred for another year. A third speaker ventured to propose a resolution, but was informed that this could not be done. Prof. Osborne Reynolds thought that graphical methods were often too complicated, and he preferred to make use of better known processes. The president, in closing the discussion, to which Prof. Hele Shaw had no opportunity to reply, said that Prof. Henrici had probably done as much for graphics as any German writer.

Tuesday.

On Tuesday several reports were taken, and Prof. Ewing exhibited and described his magnetic curve tracer, of which an account will be found in another column. A short discussion, of which we hope to give a brief report, followed. Prof. Du Bois showed a magnetic balance, and made one or two measurements to demonstrate its action. This instrument, which was exhibited in a somewhat less complete form at Frankfort, has been described briefly in our columns (*The Electrician*, Vol. XXVII., p. 634). One ingenious detail was received with applause. The length of the test bars is 122 mm., thus cancelling out the ubiquitous 4π.

After this the report of the Committee on Electrical Standards, for which we hope to find space in a future issue, was read in abstract by Mr. Glazebrook, and was followed by a brief discussion, opened by Prof. von Helmholtz. The programme was about three-quarters of an hour behind time, and was further delayed by two rather long but valuable communications from Dr. Lindeck and Dr. Kahle on "Resistance Coils" and "Clark Cells."

Many prominent members had left the meeting, which generally thinned down soon after 1 o'clock from natural causes; but as the discussion on the "Nomenclature of Units" had been adjourned for two years in succession, Dr. Oliver Lodge declined to give way a third time, and opened the debate by some remarks upon a communication which we hope to print in an early issue. Our correspondent "W. M. M." would have been interested to hear Dr. Lodge reiterate that self-induction *is* a length. The simple but revolutionary suggestion that the micro-farad should be renamed the farad, and that the name weber should be resuscitated for the unit of magnetic flux, were stoutly combated by Dr. J. Hopkinson, who also strongly objected to the word "mo." Mr. Preece contented himself, as far as the last word was concerned, by deprecating the bad habit of dropping the letter h; but while he made no proposition to the meeting, he gave notice that he intended to move at the forthcoming Congress at Chicago that the volt should be increased tenfold. It is to be hoped that if this Congress is held, and if this resolution be brought forward, that Mr. Preece will not attempt to retain the old name for a new unit, but will be sponsor for a new appellation, or, better, have a dozen or two all ready to select from.

Owing to the lateness of the hour, Mr. Preece summarised his Papers on "The Dielectric of Condensers" and on "Earth-currents" in a few words. It appears that condensers as used in telegraphy entail a considerable waste of power, and that records of earth currents, including those which we published last week, are of no use whatever. Mr. Preece's Paper will be found to contain suggestions for the proper description of these phenomena.

Prof. S. P. Thompson gave an account of some recent experiments with arc lamps surrounded by different gases. No difference in the voltage was found, and he concludes that the endothermic flame described by Prof. Crookes cannot therefore be connected with the voltage of the arc. The last Paper of the day by Messrs. Barton and Williams on "The Temperature Variation of the Magnetic Permeability of Magnetite" was dismissed in a few minutes, no discussion having been invited on the last four Papers through want of time.

Nothing of direct electrical interest occurred in Section G on Tuesday, except a description of a gas engine by Mr. Day, which is said to be capable of running at 1,000 revolutions per minute, and able to run at 500 revolutions without missing fire.

Wednesday.

Prof. Barrett opened the proceedings of Section A by giving notice that there was no report by the committee on Recalescence. A method of drawing lines of magnetic force, devised by Rev. F. T. Smith, was described by one of the secretaries. Prof. Knott described and illustrated by experiment some effects of magnetisation on the internal volume of iron and steel tubes of the same external diameter, but of different thicknesses. The results were shown by curves. The abscissæ represented magnetisation, and the ordinates volume. The whole volume was not represented, as the ordinates would have had to be about 62 miles long, but only the differences were shown. The apparent penetration of magnetism into the walls of the tube suggested that the investigation when complete will lead to very interesting results.

Prof. H. E. du Bois exhibited two polarising gratings, the one of platinum, the other of silver wires one twenty-fifth of a millimetre in diameter, and one twenty-fifth of a millimetre apart. He said that since the experiments of Hertz researches had been made which were the piers of a bridge destined to connect the continent of optics with that of electricity, and his experiments were the stones of a new pier of that bridge. The wave length of the "light" used was as great as 400, that is in the invisible ultra-red part of the spectrum, and he hoped to reach 1,000. Beyond this lay the Hertzian vibrations. An interesting discussion ensued, during which it was suggested that a similar experiment might be carried out with Leyden jar oscillations and a screen composed of pillars twenty metres diameter and twenty metres apart.

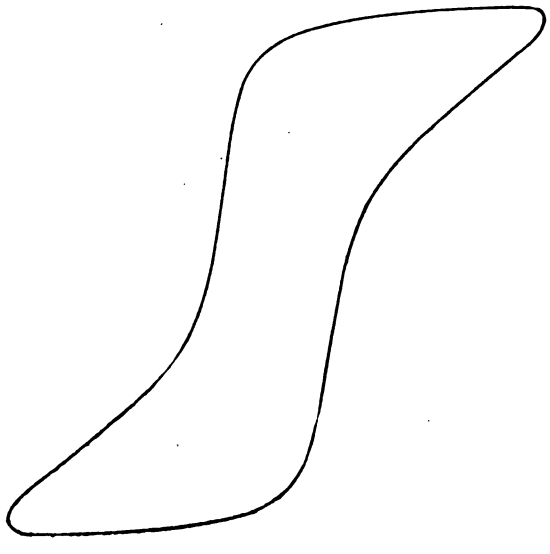
Prof. G. F. Fitzgerald gave some calculations on the rate of propagation of magnetism in iron, in which he attempted to estimate the velocity of a disturbance in a row of magnets arranged and reacting according to Ewing's theory of the structure of a magnet. He found that slow vibrations would give a short wave length, and not the contrary, as might be imagined.

After Dr. A. Keiller had described some early experiments of Mr. James Lindsay, of Dundee, in 1836, the meeting greeted with applause Dr. John Kerr, whose name is associated with the historical research on the reflection of light from a magnet. He described some experiments on dispersion in carbon disulphide under intense electrostatic stress. Among the last Papers, which were taken at the rate of about one and a-half minutes each, Prof. Ostwald made a few remarks on the general theory of energy and the kinetic explanation of all physical phenomena; and the proceedings were brought to a close by a communication from Dr. Gladstone and Mr. Hibbert, on "Some Notes on the Electromotive Force of a Secondary Battery."

Digitized by Google

Although not forming part of the Sectional Meetings of the British Association we cannot close this *resumé* of the proceedings without referring to Prof. Ewing's very interesting lecture on Monday evening entitled "Magnetic Induction." The early portion of it covered much the same ground as his discourse before the Royal Institution last year. The projection of the wobbling magnets on the screen produced roars of laughter, as it did on the former occasion. It is difficult to see what there is that is so ludicrous in the magnified shadows of a dozen little magnets; we recommend the subject to psychologists. A modification of these experiments, which was not shown at the Royal Institution, was the motion of the magnets under water, showing the effect of damping the oscillations. Several curves of magnetometer measurements of large groups of magnets were shown; but the *pièce de résistance* was the use of two curve-tracing instruments, by which the well-known hysteresis curve was projected on a screen some 30ft. square.

One of these instruments, of which a description will be found in another column, was used to show the magnetisation of solid iron bars, and a brilliant spot of light traced out the curve on the screen. A second instrument was provided with a bundle of iron wire for a core, and with this the curve could be traced no less than 20 times in a second, the curve appearing continuous. It was noticed that the rheostat which was driven by a motor ran away once or twice, and the curve assumed the shape shown in the sketch, and on several occasions the curve



was contorted into strange loops and waves. These effects are partly due to eddy currents, but appear also to be connected with mechanical inertia, and further experiment will, no doubt, enable these effects to be separated, and there seems to be good reason to hope that the instrument will be capable of running at the ordinary frequency of alternate-current machinery.

A SKETCH OF SOME OF THE ELECTRICAL PAPERS IN SECTION A.

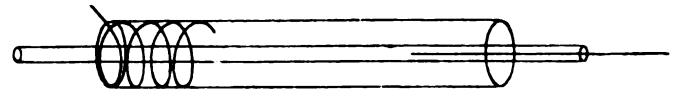
Dr. Dawson Turner exhibited an experiment showing that the passage of sparks between the terminals of an induction coil produced an effect upon a conductor in the neighbourhood of the discharge affecting its electrical resistance. The result was that the resistance was lowered temporarily. Powdered copper and a solid stick of powdered aluminium mixed with powdered resin, and contained in a glass tube, was acted upon in this way. The normal resistance was very high, but when a spark passed in the neighbourhood a couple of cells placed in circuit with it and a galvanometer showed a deflection. On shaking the tube the resistance became higher, and on leaving it at rest for an hour or so the resistance increased to the normal amount. The resin and aluminium could not be restored by shaking; it had to be warmed. There appeared to be an "orientation" of the molecules. Pressure of a mixed powdered conductor of this kind, of course, lowered its resistance; but a spark of an induction coil in the neighbourhood lowered it temporarily and left it in an unstable condition, and a slight jar would cause it to return to a condition of high resistance, while a spark at a great distance lowered it again.

Prof. G. Forbes said that he had repeated Faraday's experiment with sulphide of silver. He had used a 1-centimetre cube of the material. With a cell or two it was practically an insulator; but with 14 volts a sensible current passed, and this soon increased, until, as Faraday had shown, the resistance rapidly diminished, and the substance fused. He asked whether Hertz radiations might not in a similar way break down the resistance, and thus complete the circuit. He inquired how long the powdered conductor took to recover its high resistance.

Dr. Dawson Turner, in reply, said that aluminium powder would recover in about a quarter of an hour, if left without shaking, but a stamp of the foot on the floor or the passing of a cart in the street was sufficient to determine it.

Prof. E. Wiedemann made a communication on electrical discharges. The experiments were made with an ordinary Hertz radiation apparatus, consisting of a generator, a spark gap, a circuit from 5 to 40 metres long, terminating in a pair of plates. Near the plates, vacuum tubes were placed, and the glowing of these was studied. It was found that tubes of large diameter lighted up more readily than smaller ones. Some of the tubes were coated inside with a thin layer of platinum or silver. A second smaller tube was arranged so that it was just beyond the influence of the condenser plates, but as soon as the large tube lighted up, it acted on the small tube, and lit it up as it were with a match: but the effect could not be screened off by a dark sheet. It was requisite in these experiments to use regular and maintained oscillations of a low pitch. For this purpose the long circuit was bridged across by one or more wires, and the nearer these were to the end of the circuit, the better was the result. Under the simplest conditions of discharge the negative end glowed with a blue light, and the positive with a red; but it appeared that in these experiments the negative effects lasted for a certain time, and both ends of the tube appeared blue, while the red was in the middle. Dark spaces were seen near the electrodes, and with lower pressures these dark spaces grew until the whole tube became dark. It appeared that this was due to non-absorption rather than to non-conductivity. Prof. Wiedemann remarked that he had tried a vacuum tube shaped like a parallelopiped, and found that it would light up when placed with the longer dimension placed in the direction of the discharge, and remained dark when turned round at right angles to this position.

Mr. J. T. Bottomley said that absence of light in vacuum tubes at the beginning of a discharge was well recognised, and he asked whether the darkness observed by Prof. Wiedemann was of this kind, or if it were permanent. He had noticed that a vacuum tube, with or without terminals, would sometimes not glow, but on continuing the pumping the light would suddenly start up. The light would generally go on, but sometimes it would stop. He described one method of doing this. He had used vacuum tubes provided with a central tube open at both ends to the air (see fig.). A wire might be inserted into the



ends of the open tubes, or, better, one wire might be inserted at one end, and the other might be coiled with a few turns round the outer tube. By pushing forward the straight wire, the discharge ceased. If the tube in this condition were rubbed against the prime conductor of an electrical machine, the luminous power would be restored.

Lord Kelvin having taken the chair, Prof. Schuster read a Paper "On Primary and Secondary Cells in which the Electrolyte is a Gas." When a discharge passed in a vacuum tube, the whole interior of the tube became a conductor. He had studied the laws of that conduction, which he would call secondary conduction. Wires of different metals had

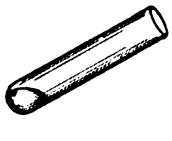
Digitized by Google

been arranged at different points in the sides of vacuum tubes. No effects of polarisation in these wires had been discovered, although carefully looked for, when these wires were of platinum, and when the tube contained nitrogen, hydrogen, oxygen, water vapour, or cyanogen. There was either no polarisation or only a very small trace. But with hydrocarbons or phosphuretted hydrogen, there were very marked phenomena of polarisation. With rarefied marsh gas for example, the main discharge in the vacuum tube was produced by about one thousand cells, and a steady current from a few cells was sent across the tube. On breaking this current and connecting the wires with a galvanometer or electrometer, a back-electromotive force of 4 or 5 volts was observed. The polarisation fell off after a time, exactly as it does with water, apparently following the same law. The resistance was enormous, and the current was very minute. The results pointed to electrolysis, and depended on the metal of the electrodes. With iron and copper there was hardly any effect, and what there was was independent of the pressure of the gas. With magnesium and aluminium the polarisation increased to an enormous extent. With magnesium, through which currents had been sent for a long time from a single cell, there was a back-electromotive force of 35 volts. A deposit was formed on both electrodes; this was a chemical compound of magnesium and carbon. The deposit was thin enough to show colours like those of oxides; but there was evidently not a mere deposit of carbon, but something of the nature of a chemical combination. Arrhenius had used electrodes of zinc and platinum in air, and had found a difference of potential of about one volt, the same as when the electrodes were immersed in a liquid electrolyte, the zinc was negative to the platinum. He had found magnesium to be the most active. In using nitrogen it should be remarked that nitrogen acts chemically on magnesium. Magnesium gave about one volt with hydrogen, and rather more than one volt with nitrogen. The magnesium was positive to the platinum.

Prof. Crookes said that he had experimented with long tubes containing rarified oxygen, this gas being the most luminous. They were exhausted, and used in the same way that Tesla had done, holding them near the terminals in the hand. If a tube had been lying quiet for some hours in a cool dark place it would remain dark, but if he did something—he did not quite know what—if he touched a terminal of the coil with the tube, or with his hand, the tube would become luminous. A tube would become non-sensitive in about half an hour or three-quarters of an hour. It might be that the gas required to be in a state of dissociation, or some other state in order to become luminous.

After some remarks from a foreign member, whose name was not announced, Prof. Arrhenius made some comments upon the experiments of Prof. Schuster, and said that certain compounds were undoubtedly formed upon the wires, but nothing was yet known about their electrolytic properties.

Prof. von Helmholtz said that he had followed the well-known electrolytic theory of Faraday. This electrical law was based upon the idea that all chemical combinations were composed of at least two atoms, one charged positively, and the other negatively. This was the ordinary hypothesis, but it applied to other cases. On the surface of glass there would be found a little stratum of gas. This gas had molecules which could be separated into positive and negative, and there was the possibility that the positive molecules could be drawn away by a positive charge, and an opposite charge might be induced through the tube. He had experimented with a glass tube containing a

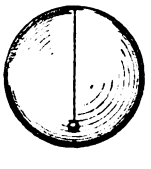


little drop of mercury (*see* figure); the tube was exhausted. When it had been left in repose for some time there was no sign of any electrical charge on it. If the tube were turned so that the mercury ran to the other end the mercury would become negative and the tube positive. There was no other friction than that of the rolling drop of mercury. The contact was more close in the exhausted tube than when a stratum of air adhered to the glass. In the construction of a mercury unit for a resistance standard the separating effect of this stratum had been recognised. The mercury column had a greater resistance, although the thickness of the stratum was quite invisible, and much too thin to show Newton's colours. A thickness of one two-thousandth of a wave-length of light gave sufficient diminution to be detected by a galvanometer. If the tube was exhausted before filling it with mercury, the resistance would be less, because the mercury was in closer contact with the glass. The lowest value of the resistance was obtained when a drop of petroleum was allowed to spread over the internal surface of the tube. Thus it could be proved that there was a measurable stratum of air on the surface of the glass tubes. If the tubes were exhausted the greater part of this went away, but some traces always reappeared.

The so-called electrification of friction was really the same as that of Volta's imperfect idea. He had dealt with the electrical difference of metals, but he did not recognise that non-conductors could exist which acted similarly, and these did not come into his "series of tensions." Some substances behave electrolytically, and if these are used in a battery there can be no equilibrium before the whole is destroyed and decomposed. It was clear that if the mercury moved, the mercury and the glass being electrically different, the glass would be electrified. The only difference was that the electrification could not move, since the glass was a bad conductor. In a voltaic pair the two conducting bodies cannot separate without a discharge, for it is impossible to separate two surfaces all over at once. There is always a last point, and then the discharge will take place. But it is another thing if a glass plate is one of these bodies. It might be considered as an insulator, for not much electrification could be transmitted to the last point. The glass, therefore, became charged.

In frictional electrical machines there was mercury or similar metallic surface, and the glass was electrified one way and the rubber the opposite way. When the glass was separated from the rubber it remained electrified, but the glass was covered with a silken piece, and a conductor conducted new electricity to that place, instead of the electricity which had been carried away. If the tube illustrated above was allowed to repose, all signs of electrification vanished. This was because the glass was not a perfect insulator. With reference to the stratum of air, he had never seen a tube completely freed from gas.

Lord Kelvin said that Prof. von Helmholtz's remarks had reminded him of an electrical night-light which was shown and described by his (Lord Kelvin's) predecessor. It was a vacuum tube containing mercury; when it was shaken it showed a light, and was said to give enough light to show the time by a watch. This was called "electrical," but it was never tested, nor had it been looked at for a long time, and no one from then till now had the slightest idea of the explanation until Prof. von Helmholtz had given it. We now understood it, and saw that there was a great tendency to electrification in the interior of the glass. Dr. Bottomley had experimented with a pendulum oscillating in a vacuum. In a ball of glass a lead ball was suspended by a silk fibre, and it continued to oscillate for 16 hours. But there was so much electricity in the interior that if the ball touched the glass it would stick there. This appeared to be due to electrification by contact.



Dr. Bottomley said that he had observed that a vacuum tube without electrodes would sometimes give no light when first brought into a field, but would suddenly acquire the property by rubbing the outside against an electrified conductor. He

Digitized by Google

asked whether Prof. Wiedemann had tried this. Prof. von Helmholtz said that the luminous effect might be seen in every barometer if it were swung. Lord Kelvin asked whether with other metals the tube would be susceptible. Prof. von Helmholtz replied that his assistant, who had been investigating the phenomenon, had only tried mercury, but had mixed it with sodium to form an amalgam, but the amalgam did not flow easily. Lord Kelvin said that now we were beginning to think that we understood some of the old phenomena; these were being brought out, and long-forgotten experiments were being explained and were becoming important.

Prof. Reinold read a Paper by himself and Prof. Rücker on the specific conductivity of thin films. He alluded to the previous Paper on this subject, and described the optical and electrical arrangements of the experiment. Plateau's soap-bubble mixture had been employed, but this was a bad conductor, and an attempt had been made to improve it by adding nitrate of potash. But they now found that films with salts and without salts gave very different results. With a film which there was good reason to suppose had a real thickness of 22·5 micromillimetres, the addition of 0·5 per cent. of KNO_3 gave a result corresponding with 14·5 micromillimetres; with 1 per cent., 13·5; and with 3 per cent., 12·4. The general result was that the specific conductivity of a film appeared to greatly exceed that of the liquid of which it was composed. This might be due to a difference of temperature, or to the absorption of gases, but it was due in some way to the tenuity. In the thinnest films which had been observed the resistance was about seven times greater than in a large mass of the same liquid.

Prof. Rücker said that the surface tension probably disturbed the mechanical equilibrium, and suggested that soap molecules being extremely complex, might be more affected by such mechanical disturbance than those of metallic salts.

ELECTRIC LOCOMOTIVES ON THE CITY AND SOUTH LONDON RAILWAY.*

BY ALEX. SIEMENS.

The object of the present communication is to place on record the performances of two electric locomotives, the most powerful of their kind, which were supplied at the end of last year by Messrs. Siemens Brothers and Co. to the City and South London Electric Railway.

In the year 1888 the Company, then called the City of London and Southwark Subway, issued a specification asking, among other things, for electric locomotives capable of developing a maximum of 100 brake H.P. Owing to financial considerations, the contract was not placed with Messrs. Siemens Brothers and Co., although a perfect agreement had been arrived at on the technical points of the question. The City and South London Company, however, invited Messrs. Siemens Brothers and Co. again in the beginning of last year to tender for locomotives in accordance with a specification practically identical with that agreed upon in 1888; and as a result two electric locomotives have been built, and are now working.

Each locomotive carries two motors, and the use of all gearing is obviated by winding the armatures of the motors on the axles of the wheels of the locomotive. This method of construction was illustrated by a model shown at work at a meeting of the Society of Arts on May 18, 1881, and had been first suggested by Sir William Siemens, who, at the time of his lamented death, was actively preparing a proposition to work the Metropolitan Railway by electric locomotives. The motors for the two locomotives were tested before they were fitted into their places by means of a Prony brake, and some of the results of this first set of tests are given in Table A.

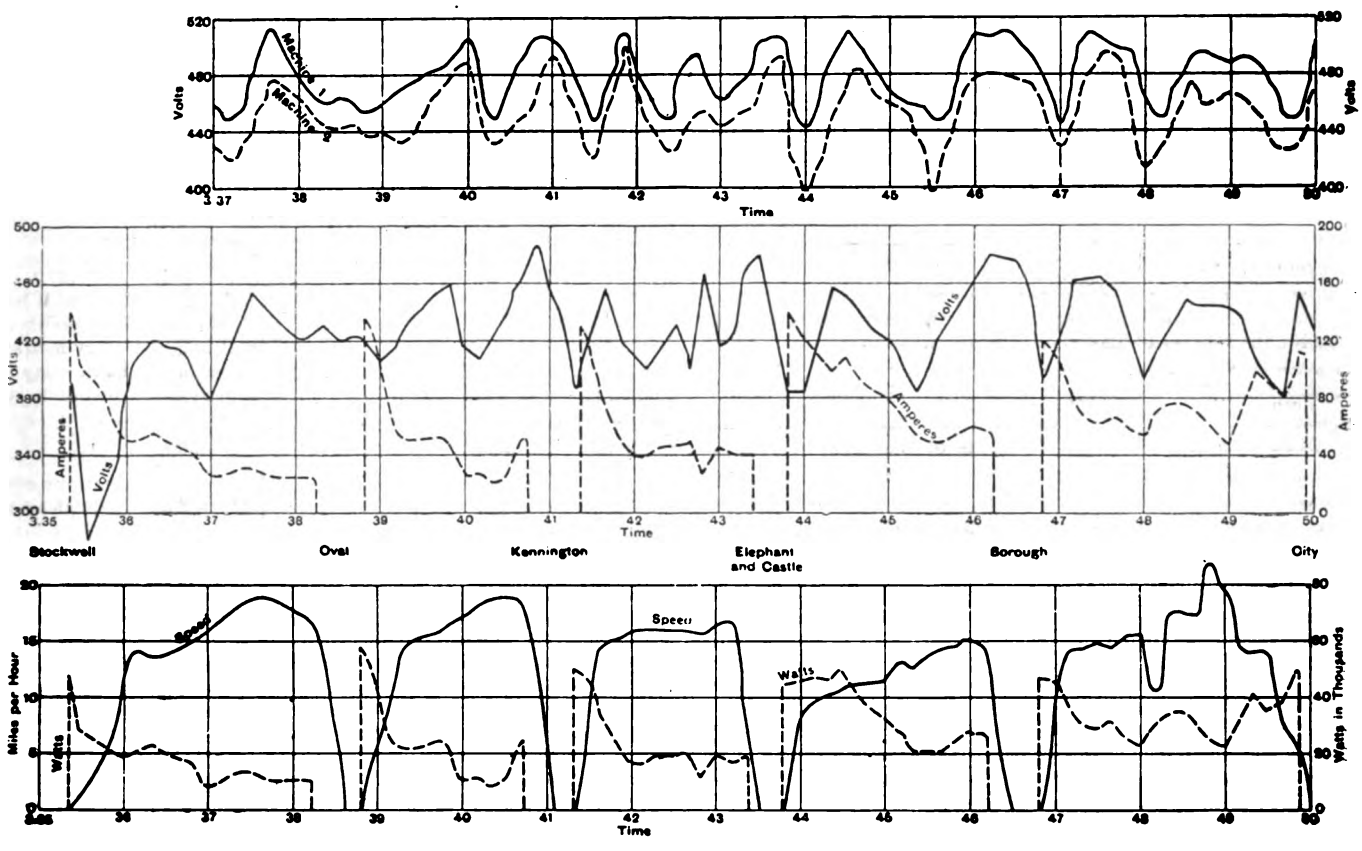


Table A.

Speed in miles per hour.	Electrical H.P. put into motor armature.	Electrical H.P. put into motor magnets.	Total electrical H.P. per motor.	Total electrical H.P. per locomotive.	Brake H.P. measured.	Efficiency per cent.

Since the two locomotives have been set to work on the railway they have had to keep the same time as the others, so that their full power cannot be utilised, but it has been found that their efficiency is satisfactory in every respect. Observations of the current and electromotive force have recently been made simultaneously by taking sets of readings on the ammeters and voltmeters, both at the generating station and on the locomotive. From these observations the curves accompanying these notes have been plotted. At the time these observations were made the locomotives had run about 8,000 statute miles, and on all four motors the brushes were wearing at the rate of about an eighth of an inch per thousand miles run, this small wear being a consequence of the motors running sparkless and practically without heating.

On examining the curves† it will be noticed that there is no similarity whatever between those representing the volts at the generating station and on the locomotives respectively; this is, however, easily explained by the consideration that the volts at the generating station are influenced by all the trains in motion at the same time, while the volts on each locomotive are principally influenced by the demand of the locomotive itself. When the train is started the current is regulated by the driver, so as not to exceed a certain amount, by means of switches inserting resistances into the main circuit, but these resistances are cut out within half a minute of starting, so that the waste of energy in the resistances is kept as low as possible. Each locomotive fully equipped weighs 13½ tons, and the weight of the train of carriages it has to draw is about 21 tons. To this the weight of the passengers has to be added.

Table B.

Final mean	313,949	739·24	14 55	424·71	49·52	12·97

A summary of the results is given in Table B, which shows that the average power developed by each locomotive requires a current of not more than about 50 amperes, although in starting as much as 140 amperes are required. This fact illustrates at the same time the peculiar difficulties which have to be grappled with in the construction of such locomotives, which have to work under conditions almost diametrically opposite to those of generating dynamos in Electric Supply Central Stations.

DISCUSSION.

Mr. J. H. GREATHEAD, engineer to the City and South London Railway Company, said the locomotives were very satisfactory, especially as regarded the armatures. It was quite obvious that it had been proved conclusively that electricity would furnish a means of dealing with the traffic in large cities in a most satisfactory way, and quite as economical as could be accomplished by great locomotives in the ordinary manner.

Prof. SILVANUS THOMPSON, in the course of his remarks, said it was a question of design and construction whether they could work the motors with field-magnets giving strong enough intensity to the magnetic field to enable them to work with small currents.

Mr. TRAILL, Antrim, then gave an account of the Giant's Causeway Electric Railway.

Prof. G. FORBES said that the success which had attended the working of the electric locomotives on the City and South London Railway was a sufficient answer to those who held up numerous accidents to armatures in the past, and pointed out that electric traction was still in an experimental stage. The way in which Messrs. Siemens had overcome all the difficulties was the obvious one of making the motor large enough. The critical thing in the working of electric locomotives for traction was not so much the efficiency for a high speed as that at the starting point. It was at the lowest speed that the greatest precaution had to be taken as to the working of the machine.

In replying to the discussion, Mr. SIEMENS said the principal loss at low speeds was caused by the resistances, but whether the motor was a little more efficient or not was really of no consequence whatever.

† [We only reproduce the curves relating to a single journey of No. 15 locomotive from Stockwell to the City. There were several more of the same kind shown by the author.—ED. *E.*]

PROF. SCHUSTER'S PRESIDENTIAL ADDRESS TO SECTION A.

[ABSTRACT.]

We are chiefly concerned here with the increase of scientific knowledge, and we may fairly ask ourselves whether it is possible by means of any systematic course of study or by means of any organisation to accelerate our progress into the dark continent of science. But in choosing the direction in which a change may best be made, I think we may learn something from the way in which Nature improves its organisms. We are taught by biologists that natural selection acts by developing those qualities which enable each species best to survive the struggle for existence; useless organs die off or become rudimentary. To apply these reflections to the questions with which we are specially concerned, I should like to see it more generally recognised that although there is no struggle for existence between different nations, yet each nation, owing to a number of circumstances, possesses it own peculiarities, which render it better fitted than its neighbours to do some particular part of the work on which the progress of science depends. Does it not seem well to let each country take that share of work for which the natural growth of its character and its educational establishment best adapt it?

As far as the work of this section is concerned the strongest domain of this country has been that of mathematical physics. But it is not to this that I wish specially to refer. Look at the work done in Great Britain during the last two centuries; the work not only in physics, but in astronomy, chemistry, biology. Is it not true that the one distinctive feature which separates this from all other countries in the world is the prominent part played by the scientific amateur, and is it not also true that our modern system of education tends to destroy the amateur? By amateur I do not necessarily mean a man who has other occupations and only takes up science in his leisure hours, but rather one who has had no academical training, at any rate in that branch of knowledge which he finally selects for study. Other names will occur to you, the most typical and eminent being that of Joule. It is not my purpose to discuss why distinguished amateurs have been so numerous in this country, but I am anxious to point out that we are in danger of losing one great and necessary factor in the origination of scientific ideas. Whatever is taught in early age must necessarily be taught in a more or less dogmatic manner, and, in whatever way it is taught, experience shows that it is nearly always received in a dogmatic spirit. It seems important, therefore, to confine the early training to those subjects in which preconceived notions are considered an advantage. If school examinations could be more general, if scientific theories could only be taught at an age when a man is able to form an independent judgment, there might be some hope of retaining that originality of ideas which has been a distinctive feature of this country, and enabled our amateurs to hold a prominent position in the history of science. At present a knowledge of scientific theories seems to me to kill all knowledge of scientific facts.

But while it is necessary to recognise the great work done by the unprofessional scientists, it seems not untimely to draw their attention to the damage done to themselves if they overstep their legitimate boundaries, and especially if they seek popular support for their theories, which have not received the approval of those who are competent to judge. An appeal from Alexander sober to Alexander drunk will not prove successful in the end.

The gradual disappearance of the amateur may be a necessary consequence of our increased educational facilities, and we must inquire whether any marked advantages are offered to us in exchange. There is one direction in which it would seem at first sight, at any rate, that a proper course of study could do much to facilitate the progress of research. On another occasion I pointed out that two parties are necessary for every advance in science, the one that makes it and the one that believes in it. If the discoverer is born, and cannot be made, would it not be possible at any rate to train the judgment of our students so that they may form a sound opinion on the new theories and ideas which are presented to them? It is too early as yet to judge in how far our generation is better in this respect than the one that has gone before them; but on closer examination it does not seem to me to be obvious that any marked improvement is possible. But looking back at the history of science during the present century, is there much evidence that great discoveries have been seriously delayed by want of proper appreciation? The point is not one of academic interest only, for the fear of re-

Digitized by Google

pressing some important new discovery has a detrimental influence in another direction. The judgment of the scientific world seems to me to be tending too much towards leniency to apparently absurd theories, because there is a remote chance that they may contain some germ of real value. A new truth will not be found to suffer ultimately by adverse and even unreasonable criticism, while bad theories and bad reasoning, supported by the benevolent neutrality of those to whose judgment the scientific world looks for guidance, are harmful in many ways. They block the way to an independent advance, and encourage hasty and ill-considered generalisations. The conclusions I should draw from the considerations I have placed before you are these: I believe that a reasonable censorship exercised by our scientific societies is good and necessary; that those whose fate it is to be called on to express an opinion on some work or theory should do so fearlessly according to their best judgment. Their opinion may be warped by prejudice, but I think it is better that they should incur the risk of being ultimately found to be wrong than that they should help in the propagation of bad reasoning. There is one matter, however, on which all opinions must agree. Worse than bad theory or logic is bad experimental work. Should we then not rigorously preserve any influence or incentive which encourages the beginner to avoid carelessness and to consider neither time nor trouble to secure accuracy? There is no doubt to my mind that the prospect of admission to the Royal Society has been most beneficial in this respect, and that the honourable ambition to see his Paper published in the *Transactions* of that Society has preserved many a student from the premature publication of unfinished work.

One of the principal obstacles to the rapid diffusion of a new idea lies in the difficulty of finding suitable expression to convey its essential point to other minds. Words may have to be strained into a new sense, and scientific controversies constantly resolve themselves into differences about the meaning of words. On the other hand, a happy nomenclature has sometimes been more powerful than rigorous logic in allowing a new train of thought to be quickly and generally accepted. A good example is furnished by the history of the science of energy. The principle of the conservation of energy has undoubtedly gained a more rapid and general acceptance than it would otherwise have had by the introduction of the word potential energy. A great theorem, which in itself seems to me to be an intricate one, has been simplified by calling something energy which, in the first place, is only a deficiency of kinetic energy. The only record I can find on the history of the expression is given in Tait's "Thermodynamics," wherein the term "statical energy" is ascribed to Lord Kelvin, and that of "potential energy" to Rankine. It would be of interest to have a more detailed account on the origin of an expression which has undoubtedly had a marked influence not only on the physics but also on the metaphysics of our time. But while fully recognising the very great advantage we have derived from this term "potential energy," we ought not, at the same time, to lose sight of the fact that it implies something more than can be said to be proved.

In the expressions we adopt to prescribe physical phenomena we necessarily hover between two extremes. We either have to choose a word which implies more than we can prove, or we have to use vague and general terms which hide the essential point, instead of bringing it out. The history of electrical theories furnishes a good example. The terms positive and negative electricity committed us to something definite; we could reckon about quantities of electricity, and form some definite notion of electrical currents as a motion of the two kinds of electricity in opposite directions. Now we have changed all that; we speak of electric displacements, but safeguard ourselves by saying that a displacement only means a vector quantity, and not necessarily an actual displacement. We speak of lines and tubes of force not only as a help to realise more clearly certain analytical results, but as implying a physical theory to which, at the same time, we do not wish to commit ourselves. I do not find any fault with this, for it is a perfectly legitimate and necessary process to state the known connection between physical phenomena in some form which introduces the smallest number of assumptions. But the great question, "What is electricity?" is not touched by these general considerations. The brilliant success with which Maxwell's investigations have been crowned is apt to make us overrate the progress made in the solution of that question. Maxwell and his followers have proved the important fact that optical and electrical actions are transmitted through the same medium. We may be said to have arrived in the subject of electricity at the stage in which optics was placed before Young and Fresnel hit on the idea of transverse vibrations; but there is no theory of electricity in the sense in which there is an elastic solid theory of light.

If the term "electrical displacement" was taken in its literal sense it would mean that the electric current consists of the motion of the ether through the conductor. This is a plausible hypothesis, and one respecting which we may obtain experimental evidence. The experiments of Rayleigh and others have shown that the velocity of light in an electrolyte, through which an electric current is passing, is, within experimental limits, the same with and against the current. The result shows that if an electrical current means a motion of the ether the velocity of the medium cannot exceed ten metres a second for a current density of one ampere per square centimetre. This, then, is the upper limit for a possible velocity of the medium. Can we find a lower limit? The answer to that question depends on the interpretation of a well-known experiment of Fizeau's, who found that the speed of light is increased if it travels through water which moves in the same direction as the light. If this experiment implies that the water carries the ether with it, and if a motion of the ether means an electric current, we should be led to the conclusion that a current of water should deflect a magnet in its neighbourhood. An experiment made to that effect would almost certainly give a negative result, and would give us a lower limit for the velocity of the medium corresponding to a given current. Such an experiment, together with that of Rayleigh, would probably dispose of the theory that an electric current is due to a translatory velocity of the medium. This would be an important step, and it would be worth while to arrive at a final settlement of the question.* The whole question of the relation between the motion of matter and motion of the medium is a vital one, and we shall probably not make any serious advances until experiment has found a new opening. But we must expect many negative results before some clue is discovered. Nor can we attach much importance to negative results unless they are made by some one in whose care and judgment we place full reliance. We should all the more, therefore, recognise the courage and perseverance of those who spend their valuable time in such investigations as Prof. Lodge has recently undertaken. That ultimately some relation will be found between moving matter and electrical action there is no reasonable doubt.

One of the most hopeful openings for new investigations has always been found in the pursuing of a theory to its logical conclusions, and there is one result of the electro-magnetic theory of light which has not, in my opinion, received the share of attention which it deserves. When sound passes through air it is propagated more quickly with the wind than against it, and we may easily find the velocity relative to the earth by combining the ordinary sound velocity with the velocity of the wind. Similarly, when any waves pass through a medium moving with uniform velocity, the waves being due to internal stresses in the medium, we may treat of the velocity of the waves independently of that of the medium, and say that the wave-velocity in the direction of motion of the medium, and relative to a fixed body, is the sum of the wave velocity, calculated on the supposition that the medium is at rest and the velocity of the medium. Prof. J. J. Thomson,† applying Maxwell's equations, has arrived at a different result for electro-magnetic waves, and has come to the conclusion that in order to get the velocity of light along a stream of flowing water we have to add to the velocity of light only half the velocity of water. The following considerations suggest themselves to me with respect to this result. Maxwell's theory is founded on certain observed effects, which all depend on the relative motion of matter. A result such as the one referred to implies actions depending on absolute motion, and appears therefore to point to something which has been introduced into the equations for which there is no experimental evidence. The only assumption clearly put down by Maxwell is that electro-magnetic actions are transmitted through the medium, and it is possible that that assumption necessarily carries Prof. J. J. Thomson's result with it. If a careful examination of the subject should show that this is the case, we are brought face to face with a serious difficulty. It is said, with justice, to be one of the great advantages of Maxwell's theory that it does away with action at a distance; but what do we gain if we replace action at a distance by something infinitely more difficult to conceive, namely, internal stresses of a medium depending on the velocity of the medium through space? I can only see one loophole through which to escape, namely, that Maxwell's medium is not homogeneous, but consists of two parts, and that if we speak of the medium as moving, we mean the motion of one of these parts relative to the other.

While we may hope to obtain important results from an investigation of the relation between what we call electricity and the medium, we must not lose sight of another avenue, namely, the relation between electricity and chemical effects. The passage of electricity through gases presents us with a complicated problem to

* Fizeau's results must either be due to the motion of matter through the medium or to the fact that moving matter carries the ether with it. If it is due to the former cause, and matter does *not* carry the ether with it, may we not consider that matter moving through the ether—that is, a relative motion of matter and ether—must produce effects equal and opposite to those of ether moving through matter? In that case the reasoning in the text would, *mutatis mutandis*, hold good.

which a number of physicists have given their attention of late years. There seems no reasonable doubt that electricity in a gas is conveyed by the diffusion of particles conveying high charges, probably identical with those carried by the electrolytic ion. The fact that this convection is a process of diffusion with comparatively small velocity is shown by the experimental result that the path of the discharge is affected by any bodily motion of the gas which conveys the current. Even the convection currents due to the heat produced by the discharge itself are sufficient to deflect the luminous column which marks the passage of the current. The most puzzling fact, however, connected with the discharge of electricity through gases consists in the absence of symmetry at the positive and negative poles. There must be some difference between a positively and negatively charged atom which seems of fundamental importance in the relation between matter and what we call electricity. A discussion of the various phenomena attending the discharge of electricity through gases seems to me to point to a conclusion which may possibly prove a step in the right direction.

A surface of separation between bodies having different conductivities becomes electrified by the passage of a current, while at the surface between two chemically distinct bodies we have, according to Helmholtz, a sheet covered at the two sides with opposite electricities. These surface electrifications are not merely imaginary layers invented to satisfy mathematical surface conditions. They can be proved to be realities. Thus, when one electrolyte floats on another, the specific resistances being different, we often observe secondary chemical effects due to the action of the ions which carry the surface electrification.

If the passage of electricity from the solid to the gas involves some work done, we must expect a double sheet of electricity at the boundary, the gas in contact with the cathode becoming positively, and that in contact with the anode negatively, electrified. *A priori* we can form no idea how a layer of gas, the atoms of which carry charges, will behave. The ordinary proof that all electrification must be confined to the surface implies that all forces act according to the law of the inverse square ; but where we have also to consider molecular forces, I see no reason why the electrification at a surface may not stretch across a layer having a thickness comparable with the mean free path of the molecule. It is here that there seems to be the fundamental difference between positive and negative electricity. A negative electrification of the gas, like that of a solid or a liquid, seems always confined to the surface, and no one has ever observed a volume electrification of negative electricity. The case is different for the positively electrified part of the gas. Wherever from other considerations we should expect a positively electrified surface sheet, we always get a layer of finite thickness. The result implies a different law of impact between positively and negatively electrified ions, but I see no inherent improbability in this. That the cathode let into a gas is surrounded by a positively electrified layer of finite thickness extending outwards must be considered as an established fact, and several of the characteristic features of the discharge are explained by it. The large fall of potential at the cathode can also be explained on the view which I have put forward ; for in order to keep up the discharge there must be a sufficient normal force at the surface, and if this force is not confined to the surface, but necessarily stretches across a finite layer, the fall of potential must be multiplied a great number of times. Similarly Goldstein has shown that some of the phenomena of the cathode are observed at every place at which the positive current flows from a wide to a narrow part of a column of gas. At such places we should expect a positive surface electrification ; and here, again, the whole appearance tends to show that we are dealing with a positive volume electrification. No corresponding phenomena are observed when the current passes from the narrow to the wide part.

The fact that in all cases experimented upon positive volume electrifications are observed but never similar negative electrifications is surely of significance.

Some of the results recently brought to light by investigations on the discharge of electricity have interesting cosmical applications. Thus it is found that such a discharge through any part of a vessel containing a gas converts the whole gas into a conductor.* There are other ways in which a gas can be put into that sensitive state in which we may treat it as a conductor, and we have every reason to suppose that the upper regions of our atmosphere are in this state. The principal part of the daily variation of the magnetic needle is due to causes lying outside the surface of the earth, and is in all probability only an electro-magnetic effect due to that bodily motion in our atmosphere which shows itself in the diurnal changes of the barometer. A favourite idea of the late Prof. Balfour Stewart will thus probably be confirmed. The difference in the diurnal range between times of maximum and times of minimum sunspots is accounted for by the fact that the atmosphere is a better conductor at times of maximum sunspots. The mention of sunspots raises a point not altogether new to this Section. Careful observation of celestial phenomena may suggest to us the solution of many mysteries which are now puzzling us. Consider, for instance, how long it would have taken to prove the universal property of gravitational attraction if the record of planetary motion had not come to the philosopher's help. And surely the most casual observation of cosmical effects teaches us how much we have yet to learn. The statement of a problem occasionally helps to clear it up ; and I may be allowed, therefore, to put before you some questions, the solution of which seems not beyond the reach of our powers.

1. Is every large rotating mass a magnet? If it is, the sun must be a powerful magnet. The comets' tails, which eclipse observations show stretching out from our sun in all directions, probably consist of electric discharges. The effect of a magnet on the discharge is known, and careful investigations of the streamers of the solar corona ought to give an answer to the question which I have put.*

2. Is there sufficient matter in interplanetary space to make it a conductor of electricity? I believe the evidence to be in favour of that view. But the conductivity can only be small, for otherwise the earth would gradually set itself to revolve about its magnetic pole. Suppose the electric resistance of interplanetary space to be so great that no appreciable change in the earth's axis of rotation could have taken place within historical times, is it not possible that the currents induced in planetary space by the earth's revolution may, by their electro-magnetic action, cause the secular variation of terrestrial magnetism? There seems to me to be here a definite question capable of a definite answer, and, as far as I can judge without a strict mathematical investigation, the answer is in the affirmative.

3. What is a sunspot? It is, I believe, generally assumed that it is analogous to one of our cyclones. The general appearance of a sunspot does not show any marked cyclonic motion, though what we see is really determined by the distribution of temperature and not by the lines of flow. But a number of cyclones clustering together like the sunspots in a group should move round each other in a definite way ; and it seems to me that the close study of the relative positions of a group of spots should give decisive evidence for or against the cyclone theory.

4. If the spot is not due to cyclonic motion, is it not possible that electric discharges setting out from the sun, and accelerating artificially evaporation at the sun's surface, might cool those parts from which the discharge starts, and thus produce a sunspot? The effects of electric discharges on matters of solar physics have already been discussed by Dr. Huggins.

5. May not the periodicity of sunspots, and the connection between two such dissimilar phenomena as spots on the sun and magnetic disturbances on the earth, be due to a periodically recurring increase in the electric conductivity of the parts of space surrounding the sun? Such an increase of conductivity might be produced by meteoric matter circulating round the sun.

6. What causes the anomalous law of rotation of the solar photosphere? It has long been known that groups of spots at the solar equator perform their revolution in a shorter time than those in a higher latitude ; but spots are disturbances which may have their own proper motions. As all causes acting within the sun might cause the angular velocity of the sun to be smaller at the equator than at other latitudes, but could not make it greater, the only explanation open to us is an outside effect either by an influx of meteoric matter, as suggested by Lord Kelvin, or in some other way. The exceptional behaviour of the solar surface seems to me to deserve very careful attention from solar physicists. Its explanation will probably carry with it that of many other phenomena.

In conclusion, I should like to return for an instant to the question whether it is possible by any means to render the progress of science more smooth and swift. We hear it said that the British Association has fulfilled its object ; we are told that it was originally founded to create a general interest in scientific problems in the towns in which it meets ; and now that popular lectures and popular literature are supposed to perform that work more satisfactorily, we are politely asked to commit the happy despatch. There is no need to go back to the original intention of those who have founded this institution, which has at any rate adapted itself sufficiently well to the altered circumstances to maintain a beneficial influence in scientific research. The free discussion which takes place in our Sections, the interchange of ideas between men who during the rest of the year have occupied their minds, perhaps too much, with some special problem, the personal intercourse between those who are beginning their work with sanguine expectations, and those who have lost the first freshness of their enthusiasm, should surely one and all ensure a long prosperity to our meetings. If we cannot claim any longer to sow the seeds of scientific interest in

* An experiment by Hittorf (*Wied. Ann.*, VII., p. 614) suggested the probability of this fact, which was proved independently by Arrhenius and myself.

* The efforts of Mr. Bigelow have a bearing on this point, also some remarks which I have made in a lecture before the Royal Institution (*Proc. Roy. Inst.* 1891), but nothing decisive can be asserted at present.

the towns we visit, because the interest is established, we can at any rate assure those who so kindly offer us hospitality that they are helping powerfully in the promotion of the great object which we all have at heart.

PROF. UNWIN'S PRESIDENTIAL ADDRESS TO SECTION G.

[ABSTRACT.]

The year just passed is not one unmemorable in the annals of engineering. The broad-gauge system has been extinguished. The past year has seen the completion of the magnificent scheme of water supply for Liverpool from the Vyrnwy. This is one of the largest and most striking of those works of municipal engineering rendered necesssary by the growth of great city communities, and made possible by their wealth and public spirit. Since the construction of the Vyrnwy dam, another very large dam, the Tansa dam, has been completed in Bombay. In the United States a still greater work of the same kind has been commenced on the Croton river, in connection with the water supply of New York. A scheme of water supply for Manchester from Lake Thirlmere, in Westmoreland, is approaching completion. Birmingham is likely to carry out another work of the same kind, and London, at a greater distance from pure water sources, and under greater difficulties from the complexity of existing interests, has come to realise that, within 50 years, a population of 12½ millions will probably have to be provided for. To supply such a population, a volume of water is required ten times as great as the whole available supply from Lake Vyrnwy.

Here in Edinburgh one remembers that the birthplace of the steam-engine is near at hand. A century and a quarter ago, James Watt made an invention which has profoundly influenced all the conditions of social, national, commercial, and industrial life. So great was Watt's insight into the action of the engine that he was able to leave it so perfect that, except in one respect, little remained for succeeding engine builders, except to perfect the machines for its manufacture, to improve its details and to adapt it to new purposes. Now it very early became clear that there were two directions of advance which ought to secure greater economy. Simple mechanical indications showed that increased expansion ought to ensure increased economy. Thermo-dynamic considerations indicated that higher pressures, involving a greater temperature range of working, ought to secure greater economy. But in attempting to advance in either of these directions, engineers were more or less disappointed. Some of Watt's engines worked with 5lb. of coal per indicated horse-power per hour. Many engines with greater pressures and longer expansions have done but little better. The history of steam-engine improvement for a quarter of a century has been an attempt to secure the advantages of high pressures and high ratios of expansion. The difficulty to be overcome has proved to be due to the same cause as the inefficiency of Watt's model engine. The separate condenser diminished, but it did not annul the action of the cylinder wall. The first experiments which really startled thoughtful steam engineers were those made by Mr. Isherwood between 1860 and 1865. Very little later than this M. Hirn undertook, in 1871-5, his classical researches on the action of the steam in an engine of about 150 I.H.P. Experiments of greater accuracy or completeness, or of a greater insight into the conditions which were important, have never since been made. Hirn originated a complete method of analysis of an engine test, showing at every stage of the operation the heat accounted for and a balance of heat unaccounted for; and the latter proved to be a very considerable quantity. Meanwhile theoretical writers, especially Rankine and Clausius, had been perfecting a thermo-dynamic theory of the steam engine, based primarily on the remarkable and irrefragable principle of Carnot. The result of Hirn's analysis was to show that these theories, applied to the actual steam engine, were liable to lead to errors of 50 or 60 per cent., the single false assumption being made that the interaction between the walls of the cylinder and the steam was an action small enough to be negligible.

In this country Mr. Mair Rumley, following Hirn's method, made a series of experiments on actual engines with great care and accuracy and completeness. All these experiments demonstrated the fact of a large initial condensation of steam on the walls of the cylinder, alike in jacketed and unjacketed engines. This condensed steam is re-evaporated partially during expansion, but mainly during exhaust, and serves as a mere carrier of heat from boiler to condenser, in conditions not permitting its utilisation in producing work. It became clear from Hirn's experiments, if not from the earlier experiments of Isherwood, that for each engine there is a particular ratio of expansion for which the steam expenditure per horse-power is least. Prof. Dery has since deduced from them that the practical condition of securing the greatest efficiency is that the steam at release should be nearly dry. In producing that dryness the jacket has an important influence. In spite of much controversy amongst practical engineers about the use of the jacket, it does not appear that any trustworthy experiment has yet been adduced in which there was an actual loss of efficiency due to the jacket. In the older type of comparatively slow engines it is a rule that the greater the jacket condensation the greater the economy of steam, even when the jacket condensation approaches 20 per cent. of all the steam used. It appears, however, that as the speed of the engine increases, the influence of the jacket diminishes, so that for any engine there is a limit of speed at which the value of the jacket becomes insignificant.

Among steam-engine experiments directed specifically to determine the action of the cylinder walls, those of the late Mr. Willans should be specially mentioned. Mr. Willans's death is to be deplored as a serious loss to the engineering profession. His steam-engine experiments, some of them not yet published, are models of what careful experiments should be. They are graduated experiments designed to indicate the effect of changes in each of the practically variable conditions of working. They showed a much greater variation of steam consumption (from 46lb. to 18lb. per indicated horse-power hour) in different conditions of working than, I think, most practical engineers suspected, and this has been made more significant in later experiments, on engines working with less than full load. The first series showed that in full-load trials the compound was superior to the single engine in practically all the conditions tried, but that the triple was superior to the compound only when certain limits of pressure and speed were passed.

As early as 1878 Prof. Cotterill had shown that the action of a cylinder wall was essentially equivalent to that of a very thin metallic plate, following the temperature of the steam. The exceedingly rapid dissipation of heat from the surface during exhaust especially being due to the evaporation of a film of water initially condensed on its surface. Recently Prof. Cotterill has been able to carry much further the analysis of the complex action of condensation and re-evaporation in the cylinder, and to discriminate in some degree between the action of the metal and the more ambiguous action of the water film. By discarding the less important actions, Prof. Cotterill has found it possible to state a semi-empirical formula for cylinder condensation in certain restricted cases which very closely agrees with experiments on a wide variety of engines. It is to be hoped that, with the data now accumulating, a considerable practical advance may be made in the clearing up of this complex subject. Interpreted by what is already known of thermo-dynamic actions, there are very few trustworthy engine tests which do not fall into a perfectly intelligible order.

There is only one known method, not now much used, by which the cylinder condensation can be directly combated. Thirty years ago superheating the steam was adopted with very considerable increase of economy. It is likely that it was thought by the inventor of superheating that an advantage would be gained by increasing the temperature range. If so, his theory was probably a mistaken one. For the cooling action of the cylinder is so great that the steam is reduced to saturation temperature before it has time to do work, but the economy due to superheating was unquestionable, and was very remarkable, considering how small a quantity of heat is involved in superheating. The heat appears to diminish the cylinder-wall action so much as almost to render a jacket unnecessary. The plan of superheating was abandoned from purely practical objections, the superheaters then constructed being dangerous. Recently superheating has been tried again at Mulhouse by M. Meunier, and his experiments are interesting because they are at higher pressures than in the older trials and with a compound engine. It appears that even when the superheater was heated by a separate fire there was an economy of steam of 25 to 30 per cent. and an economy of fuel of 20 to 25 per cent., and four boilers with superheating were as efficient as five without it. It may be pointed out as a point of some practical importance that if a trustworthy method of superheating could be found, the advantage of the triple over the compound engine would be much diminished. For marine purposes the triple engine is perfectly adapted. But for other purposes it is more costly than the compound engine, and it is less easily arranged to work efficiently with a varying load. There does not seem much prospect of exceeding the efficiency attained already in the best engines, though but few engines are really as efficient as they might be, and there are still plenty of engines so designed that they are exceedingly uneconomical. The very best engines use only from 12lb. to 13lb. of steam per indicated horse-power hour, having an absolute efficiency reckoned on the indicated power of 16 per cent., or reckoned on the effective power, 13 per cent. The efficiency, including the loss in the boiler, is only about 9 per cent. But there are internal furnace engines of the gas-engine or oil-engine type in which the thermal efficiency is double this.

In his interesting address to this Section in 1878, Mr. Easton expressed the opinion that the question of water-power was one

Digitized by Google

deserving more consideration than it had lately received, and he pointed to the variation of volume of flow of streams as the principal objection to their larger utilisation. Since that time the progress made in systems of transporting and distributing power has given quite a new importance to the question of the utilisation of water-power. There seems to be a probability that in many localities water-power will, before long, be used on a quite unprecedented scale, and under conditions involving so great convenience and economy that it may involve a quite sensible movement of manufactures towards districts where water-power is available. The whole tendency of the conditions created by the use of steam power has been to concentrate the industrial population in large communities, and to restrict manufacturing operations to large factories. The whole social conditions of manufacturing centres have been profoundly influenced by these two conditions—that coal for raising steam can be easily brought to any place where it is wanted, and that steam power is more cheaply produced on a large scale than on a small scale. It looks rather, just now, as if facilities for distributing power will to some extent reverse this tendency. Let me first point out that water power, where it is available, is so much cheaper and more convenient than steam power that it has never been quite vanquished by steam power. I find, from a report by Mr. Weissenbach, that, in 1876, 70,000 H.P. derived from waterfalls were used in manufacturing in Switzerland. According to a census in 1880, it appears that the total steam and water power employed in manufacturing operations in the United States was 3,400,000 H.P. Of this, 2,185,000 H.P., or 64 per cent., was derived from steam, and 1,255,000 H.P., or 36 per cent., from water. In the manufacture of cotton and woollen goods, of paper, and of flour, 760,000 H.P. were obtained from water, and 515,000 H.P. from steam. If the statistics could be obtained from other countries, I believe it would be found that a very large amount of water power is actually made available. With a very limited exception, all the water-power at present used is employed in the neighbourhood of the fall where it is generated. If means were available for transporting the power from the site of the fall to localities more convenient for manufactures, there can be no doubt that a much larger amount of water-power would be used, and the relative importance of water and steam-power in some countries would probably be reversed. It is because recent developments seem to make such a transport of power possible without excessive cost, and without excessive loss, that a most remarkable interest has been excited in the question of the utilisation of water-power. Take the case of Switzerland, for instance. At the present time Switzerland is said to pay to other countries £800,000 annually for coal. But the total available water-power of Switzerland is estimated at no less than 582,000 H.P., of which, probably, only 80,000 are at present utilised.

First, then, let me say a few words as to modes of distributing power which it is possible to adopt. Wire rope transmissions are of great mechanical simplicity, and the loss of power in transmission is exceedingly small. They are extremely suitable for certain cases where a moderate amount of power has to be transmitted a moderate distance—to one or to a few factories. On the other hand, they become cumbrous if the amount of power transmitted exceeds 600 H.P. or 1,000 H.P. The wear of the ropes, which only last a year, has proved greater than was expected, and is a source of considerable expense.

The practical introduction of a system of distributing power by pressure water is due to Lord Armstrong. Such a system involves central pumping station, a series of distributing mains, and suitable working motors. From its first introduction the peculiar advantages of this system for driving intermittently working machines, such as lifts, dock machinery, railway cranes, and hauling gear, became obvious. But, with intermittent working machines, there arose the need of an appliance for storing energy during periods of minimum demand, and restoring it in periods of maximum demand. The invention of the accumulator by Lord Armstrong made the system of hydraulic transmission a success, and at the same time fixed its character as a system specially adapted for those cases where intermittent work is required to be done. Lord Armstrong's system of hydraulic distribution by water at a pressure of 700lb. or 800lb. per square inch, with the use of accumulators for equalising the variations of supply and demand, has now been widely adopted. The most extensive scheme of that kind hitherto executed is the important scheme carried out by the Hydraulic Power Company. Over 50 miles of pressure mains have now been laid in the streets of London. The Falcon Wharf pumping station contains four sets of compound pumping engines, each of 200 H.P. Two additional pumping stations have now been erected, and 1,500 lifts are worked from the pressure mains. The minimum charge for water is 2s. per 1,000 gallons. This rate of charge is economical for such machines as lifts, but it would be extravagant for machines working continuously. It would be equivalent to a charge of nearly £50 per horse-power per year of 3,000 working hours, apart from interest and maintenance of machines.

But neither teledynamic transmission nor hydraulic transmission have proved suitable as methods for the general distribution of motive power from central stations. Distribution by steam and distribution by heated water have both been tried in the United States, but not with very remarkable success. Only two other methods are available, distribution by compressed air and distribution by electricity. For many years compressed air has been used to distribute power in tunnelling and mining operations to considerable distances. It is only recently that it has been used as a general method of distributing power to many consumers. It is through experience gained and improvements carried out in the remarkable system now at work in Paris, and known as the Popp system, that the great advantages of compressed air distribution have been proved. In 1889 steam air compressors of 2,000 H.P. were at work, and additional compressors were under construction. The pressure at that time was five atmospheres, and the largest air mains were 12in. in diameter. Ingenious and simple rotary machines were used as air motors for small powers, and for larger powers any ordinary steam-engine was converted into an air motor. Prof. Kennedy made tests in 1889. He found that a motor four miles from the compressing station indicated 10 H.P. for 20 I.H.P. expended at the compressing station, an efficiency of 50 per cent. only. There were then 225 motors worked from the air mains. Since 1889 more extended investigations have been made by Prof. Riedler, of Berlin, and the chief part of the waste of work has been traced to inefficiency of the air compressors. Compound air compressors of much higher efficiency have now been constructed. The plant at the St. Fargeau station has been increased to 4,000 H.P. A new station has been erected on the Quai de la Gare, intended ultimately to contain compressors of 24,000 H.P Compressors of 10,000 H.P. are already under construction. Compressed air transmission, whether or not it is the most economical system, is undoubtedly applicable for the distribution of power on a very large scale and to very considerable distances. There is nothing in any of the appliances which is novel or imperfectly understood. The air is used in the consumer's premises in machinery of well-understood types, and old steam engines can be converted into air motors without difficulty and without alteration of existing transmissive machinery in the factories. Not least important, the air can be measured with accuracy enough for practical purposes by simple meters, and charged for in proportion to the power consumed. Air compressors and air motors are not as efficient as dynamos and electric motors, but in one respect distribution by air and electricity are similar. For distances which are not more than a few miles the loss of energy in transmission is small enough to be insignificant.

About electrical distribution of power I shall not venture to say much, partly because I am not an electrical expert, partly because it has been lately pretty fully discussed. But electrical power distribution to private consumers for industrial purposes has not yet made as much progress as might have been expected.

I have spoken of the growth of a demand for power distributed in a convenient form in towns. The power distribution in London, Manchester, Birmingham, and Liverpool by pressure water, and that by compressed air in Paris, shows how rapidly, when power is available, a demand for it arises. A striking instance may be found in the small town of Geneva. In 1871, soon after the completion of the earlier system of low-pressure water supply, Colonel Turrettini applied to the Municipal Council to place a pressure engine on the town mains for driving the factory of the Society for Manufacturing Physical Instruments. The plan proved so convenient that nine years after, in 1880, there were in Geneva 111 water-motors supplied from the low-pressure mains, using 34,000,000 cubic feet of water annually, and paying to the municipality nearly £2,000 a year. The cost of the power was not low. It was charged at a rate equivalent to from £36 to £48 per horse-power per year of 3,000 working hours. But even the high price did not prevent the use of power so conveniently obtainable. Since then a high-pressure water service has been established, the water being pumped by turbines in the Rhone. From this high-pressure service power is supplied more cheaply. On the high-pressure system the cost of the power is about 0·7d. per horse-power hour, or £8 per horse-power for 3,000 working hours. In 1889 the annual income from water sold for power purposes on the low-pressure system was £2,085, and on the high-pressure system £4,500. On the high-pressure system the receipts in 1889 were increasing at the rate of £880 per year. In 1889 the motive power distributed on the high-pressure system alone amounted to 1,500,000 H.P. hours, there being 79 motors of an aggregate working power of 1,279 horses. In Zurich there is a quite similar system and power, amounting to 9,000,000 H.P. hours in the year, distributed hydraulically to various consumers who pay a rental of £1,200 per annum. It will be noted that all this power in Geneva and Zurich is obtained from water which has been pumped, and it is the low cost of the water power which does the pumping which makes this possible. But further, in both Geneva and Zurich the whole of the dynamos

Digitized by Google

supplying electric light are also driven by turbines using pumped water. The convenience of this arises in this way. The fall obtainable in the river in both cases is a small one, and varies. Large turbines are required, and these cannot work at a constant speed. Further, it is expensive to use these large low-pressure turbines to drive directly dynamos which only work with a considerable load for a short portion of the day. The low-pressure turbines in the river are therefore used to pump water to a high-level reservoir, and they work with a constant load all the 24 hours. From the high-level reservoir water is taken as power is required to drive the dynamos, and the turbines driving the dynamos are small high-pressure turbines, working always on a constant fall at a regular speed, and easily adjusted by a governor to a varying load. The system seems a roundabout one, but it is perfectly rational, effective, and economical.

Few persons can have seen Niagara Falls without reflecting on the enormous energy which is there continuously expended, and for any useful purpose wasted. The exceptional constancy of the volume of flow, the invariability of the levels, the depth of the plunge over the escarpment, the solid character of the rocks, all mark out Niagara as an ideally perfect water-power station; while, on the other hand, the remarkable facilities of transport, both by steam navigation on the lakes and by four systems of railway, afford commercial advantages of the highest importance. From a catchment basin of 240,000 square miles, an area greater than that of France, a volume of water amounting to 265,000 cubic feet per second descends from Lake Erie to Lake Ontario, a vertical distance of 326ft., in 37½ miles. Supposing the whole stream could be utilised, it would supply 7,000,000 H.P. This is more than double the total steam and water power at present employed in manufacturing industry in the United States. It was not, however, till about 30 years ago that any systematic attempt was made to utilise part of the water-power of the Falls. Then a canal was constructed from Port Day, about three-quarters of a mile above the Falls, to a forebay or head-race along the cliff overlooking the lower river. In 1874 the Cataract Mill was established, taking power from this canal, and other mills were gradually erected till about 6,000 H.P. was utilised. These mills have been exceedingly prosperous. but since the growth of a feeling against the disfigurement of the Falls it has become impossible to extend works of the same kind. In 1886 the Niagara Falls Company was incorporated. In 1889 the Cataract Construction Company was formed to mature and carry out the constructional works required. The present plans contemplate the utilisation of 100,000 effective horse-power. The principal work of construction is a great tunnel, 7,250ft. long, which is to form a tail-race to the turbines, starting from land belonging to the company, and discharging into the lower river. The tunnel is 19ft. by 21ft., or 386 sq. ft. in area, inside a brickwork lining 16in. thick. The base of the tunnel is 205ft. below the sill of the head gate, and permits a fall of 140 to be rendered available at the turbines. The brickwork of the tunnel is lined for 200ft. from the mouth with cast-iron plates. The tunnel has been excavated with remarkable rapidity with the aid of drills worked by compressed air. The main head-race, about 200ft. wide, will run for about 5,000ft., parallel with the river, having entrances from the river at both ends. Near the lower reach the Soo Paper Company is already arranging to utilise 6,000 H.P., discharging the water from the turbines through a lateral tunnel into the main tunnel. Near this lower reach will also be placed two principal power stations, from which power will be distributed, either electrically or otherwise, in ways not yet fully determined. The first turbines to be erected in these power stations will be twin turbines of the outward-flow type of 5,000 effective horse-power. These turbines have a vertical shaft for driving dynamos or other machinery placed above ground. According to original plans it was intended to distribute water by surface canals to different power users, each of whom would sink his own turbine pits, connected below by lateral tunnels to the main discharge tunnel. Some of the power at Niagara will undoubtedly be used in this way; and in the case of industries requiring a large amount of power it will be economical to purchase a site and water rights. Such a plan is, however, not adapted to smaller factories. Obviously for them it would be more economical to develop the power in one or more central stations by turbines of large size under common management. Further, once given the means of distributing power instead of water, an important extension of the project becomes possible. Besides supplying power to industries which may locate themselves at Niagara, the power may be transmitted to the existing factories in Buffalo and Tonawanda. Arrangements are already proceeding to transmit 3,000 H.P. to Buffalo, a distance of 18 miles, to work an electric lighting station.

In 1890, the President of the Niagara Construction Company visited Europe to examine systems of power distribution. It was in consequence of this visit that the important modification of the plans of the Company involved in the substitution, to a large extent, of a system of power distribution for a system of water distribution came to be adopted. The American engineers were anxious to obtain the best European advice as to the methods best suited to the local conditions. A commission was formed, consisting of Lord Kelvin, Dr. Coleman Sellers, Prof. Mascart, and Colonel Turrettini, and an invitation was given to engineers and engineering firms in Europe and America to send in competitive projects for the utilisation of the power at Niagara and its distribution to different consumers at Niagara and in Buffalo by electrical or other means. Many of the plans sent in were worked out with great care and completeness. As to the hydraulic part of the projects there was some approach to general consent as to the arrangements to be adopted, but as to the methods of distributing the power there was an extraordinary diversity. Generally the commission reported in favour of electrical distribution, with perhaps a partial use of compressed air as an auxiliary method. Generally also they reported in favour of methods of distribution by continuous currents in preference to alternating currents. Since the date at which the commission reported, the Frankfort-Lauffen experiment has been made, and in the opinion of some electrical engineers a distinct advance has been achieved in the use of alternating currents at high potential. The company has not yet decided to adopt any plan for the central stations except in a tentative way. One or more turbines of 5,000 H.P. are to be erected, and probably at first this power will be distributed to Buffalo by an alternating-current system. The cost of a steam horse-power at Buffalo is reckoned at $35 per annum. I believe the company will be able to deliver power at from $10 for large amounts and a greater price for small amounts, this price being reckoned for 24-hour days. The new industry of electric lighting has made necessary the provision of large amounts of motive-power. Electric traction similarly depends on the supply of motive-power. New chemical and metallurgical processes are being introduced which entirely depend for their commercial success on the supply of motive power at a low price. Niagara is likely to become not only a seat of large manufacturing operations of familiar types, but also the home of important new industries.

LIST OF THE ELECTRICAL PAPERS READ AT THE BRITISH ASSOCIATION.

GERMAN CENTRAL STATION DATA.

The following table is compiled from one published by Herr Kittler:—

Town.	Maxim'm amperes available A (1891)	Day of maximum consumption (1891).		Ratios (1891).		Ratios. Average since station opened.	
		Amp.hrs. Q	Amperes a	$\frac{a}{A}$	$\frac{Q}{A}$	$\frac{a}{A}$	$\frac{Q}{A}$
Berlin	64,000	307,000	36,900	0·58	4·80	0·72	5·66
Hamburg	6,350	34,000	3,650	0·58	5·37	0·58	5·40
Barmen.....	3,141	7,086	1,190	0·38	2·24	0·41	2·74
Breslau	5,000	21,240	3,160	0·63	4·24	0·63	4·24
Darmstadt ...	3,736	10,410	2,260	0·60	2·79	0·55	2·92
Düsseldorf ...	5,754	18,720	2,940	0·51	3·26	0·51	3·26
Elberfeld	4,905	19,218	3,500	0·71	3·92	0·77	4·35
Hanover	5,836	20,533	3,200	0·55	3·52	0·55	3·52
Knöigsberg ...	2,918	11,500	1,870	0·64	3·94	0·64	3·94
Lübeck	2,325	7,900	1,220	0·52	3·39	0·66	4·62
Mulhouse	3,468	8,646	1,600	0·46	2·49	0·43	2 88
Stettin	3,109	13,380	1,900	0·61	4·30	0·61	4·30

The average for the twelve towns comes to $\frac{a}{A} = \cdot 59$, and $\frac{Q}{A} = 3 \cdot 99$. An examination of these figures shows that much the same conditions obtain in Germany as in this country in regard to central stations, viz., the maximum demand at any instant never exceeds 75 per cent., and rarely exceeds 60 per cent. of the maximum possible supply; the largest daily output is rarely more than equivalent to five hours of the machinery running at top load.

LEGAL INTELLIGENCE.

Lane Fox v. Kensington and Knightsbridge Electric Lighting Company.

JUDGMENT.

In the Court of Appeal on Wednesday, judgment was delivered by Lord Justice Lindley, Lord Justice Lopes, and Lord Justice Kay in the case of "Lane Fox v. the Kensington and Knightsbridge Electric Lighting Company."

LORD JUSTICE LINDLEY said: This is an appeal by the plaintiff against a judgment of Lord Justice A. L. Smith dismissing an action brought for the infringement by the defendants of a patent belonging to the plaintiff. As usual in such cases, the defendants denied the infringement, and denied the validity of the plaintiff's patent, on the ordinary grounds of want of subject matter, want of novelty, want of utility, insufficiency of the specification; and, in addition to these, the defendants contended that the nature of the invention as described in the provisional specification was not the same as that described in the complete specification, at any rate after it had been amended and put into its present form. Lord Justice Smith decided in the defendants' favour on the last point, but he also came to the conclusion that the invention as described could not be usefully worked; and that the directions to work it were insufficient. He, however, decided the other points in favour of the plaintiff, and held that if the patent had been valid the defendants would have infringed it. A cross notice of appeal was given by the defendants, and the whole case was argued at great length before this Court by Mr. Lane Fox in person on the one side, and by Mr. Wallace as counsel for the defendants on the other. The Court was supplied with a printed copy of the shorthand notes of the evidence in the Court below, and of the arguments of counsel on the trial of the action and of the judgment of the learned Judge. All these I have carefully read and studied since the argument in this case was closed.

The plaintiff's patent, as described in his original specification, was for "improvements in obtaining light by electricity, and in conveying, distributing, measuring, and regulating the electric current for the same, and using means or apparatus employed therein." The provisional specification was filed on October 9, 1878, and the complete specification was filed on April 9, 1879. Owing to subsequent disclaimers and amendments, which it will be necessary to examine more carefully by-and-by, the only part of the patent which has to be considered is that relating to the distribution and regulation of electric currents for purposes of lighting. In order to understand the nature of the plaintiff's invention, and the objections taken to the validity of the patent, it is necessary to ascertain what was the state of knowledge as regards electric lighting in 1878. This is by no means an easy matter; for since that time much has been learned, vast improvements have been made, and the progress has been so fast and yet so gradual and continuous, that there is great danger in supposing that what is now plain and well known was plain and well known then. The evidence given in the case shows that the following matters were well known in 1878:—(1) That electricity could be used for lighting purposes; (2) that the arc or brush light was known and in course of being perfected; (3) that incandescent lighting was foreseen as possible and probable, and that many persons were trying to discover how to effect it; (4) that electric generators and what are now called dynamos were well known; (5) that Planté's secondary batteries, capable of being charged by an electric current, and of storing electricity (*i.e.*, of remaining inert), and of giving electricity out when wanted, were well known, and had been used for lighting; (6) that the voltage of the electric current given off by such batteries could be increased or diminished by adding or removing cells; (7) that in order to obtain and maintain an electric current a complete conducting circuit was necessary; (8) that for currents of low tension the earth itself might be used for a return conductor; (9) that earth, or "an earth," was a technical expression used to denote any suitable return conductor; and (10) that any competent electrician would know that if in any particular case he could use the earth itself as a return conductor, some other return conductor would have to be provided. On the other hand, the evidence shows that in 1878 it was not known how to construct an incandescent electric lamp for any generally useful purpose. It was not known to be important for the purpose of lighting with such lamps that the current supplying them should be kept at a constant pressure of about 100 volts; nor was it known that good results for incandescent electric lighting would be obtained by using secondary batteries, such as Planté's, in conjunction with dynamos. Further, in 1878, dynamos did not work so smoothly as they do now; that some better method of regulating the action of the engines used to drive them was necessary, or at least desirable. Lastly, it was not known that for lighting large districts with incandescent lamps with electrical currents of high tension the earth could not be used as a return conductor. Such being the state of knowledge in 1878, the plaintiff claims by his patent to have done three things which were new and useful, viz. (1), he claims to have invented a lamp which would answer the purpose; (2) he claims to have invented a method of keeping the electromotive force of the current in the mains constant at about 100 volts; (3) he claims to have invented a method of better regulating the engines which drove the dynamos. The lamp has been since replaced by cheaper and better ones, and has been disclaimed. The regulator has become unnecessary by reason of improvements in engines and dynamos, and has been disclaimed, but it was a very important part of the original invention. There remains the invention for keeping the electromotive force of the current constant. This invention is the one which has to be considered in this action.

Digitized by Google

An invention is not the same as a discovery. When Volta discovered the effect of an electric current from his battery on a frog's legs he made a great discovery, but no patentable invention. Again, a man who discovers that a known machine can produce effects which no one knew could be produced by it before may make a great and useful discovery, but if he does no more his discovery is not a patentable invention. ("Britain *v.* Hirsh," 5 Patent Cases, 232; "Harwood *v.* Great Northern Railway Company," House of Lords, 654; "Horton *v.* Mahon," 12 C.B. N.S., 437; "Saxby *v.* Gloucester Wagon Company," 7 Q B., 305.) He has added nothing but knowledge to what previously existed. A patentee must do something more: he must make some addition, not only to knowledge, but to previously known inventions, and must so use his knowledge and ingenuity as to produce a new and useful thing or result, or to produce a new and useful method of producing an old thing or result. On the one hand, the discovery that a known thing, such, for instance, as a Planté battery, can be used for a purpose for which it has never been used before, is not alone a patentable invention; but, on the other hand, the discovery how to use such a thing for such a purpose will be a patentable invention. There is novelty in the mode of using it as distinguished from novelty and purpose, or if any new appliance is necessary for using it for its new purpose, and if such mode of user or modification or appliance involves any appreciable merit. It is often extremely difficult to draw the line between patentable inventions and non-patentable discoveries, but I have endeavoured to state the distinction as I understand it, and as far as is necessary for the purposes of the present case. I have, of course, been guided by the previous decisions on the subject, and especially by "Harwood *v.* Great Northern Railway Company" (11 House of Lords, 656), which is the most instructive of them all.

I have been induced to make these observations in order to apply them to the question whether the plaintiff's invention was anything more than a discovery that Planté's cells can be usefully employed for incandescent lighting. If it is not, his invention will not be the subject matter of a patent. What, then, is the nature of his invention, as described in his original specifications? It certainly is not for the mere use of Planté's batteries in connection with dynamos. It is for the use of them "as described," which is a very different matter. Read the provisional specification, page 2, line 12, to the end; and the complete specification, page 4, line 11, to the end, omitting that part which relates to measuring. I cannot read these specifications without coming to the conclusion that the plaintiff thought he had discovered how to overcome one of the greatest difficulties in incandescent lighting. He points out that the electromotive force of the electric conducting mains should be kept constant at about 160 volts by means of dynamos and secondary batteries, used as described at various places and in conjunction with the regulator, which he says is necessary. That is his discovery, and the nature of his invention, as stated by himself. It is not put in this simple form; it is mixed up with the mode of carrying the invention out. The plaintiff not merely discovered that Planté's secondary batteries could be usefully employed for incandescent lighting, but he showed the importance of keeping the electromotive force in the mains constant at the best voltage, and he claims to have shown how practically the desired result could be obtained, which no one knew before. As regards the nature of the invention as originally described, and as regards its being the proper subject matter for a patent, my decision is in favour of the patentee, provided always that his invention proves practicable. This accords with the view taken by Lord Justice Smith. But this view of the plaintiff's invention is of no use to the plaintiff, for neither the defendants nor anyone else use this invention as it was originally described. The plaintiff now claims something very different, viz., the use of secondary batteries in conjunction with dynamos for the purpose of keeping the electromotive force constant in the mains at about 100 volts. Lord Justice Smith held this to be an invention very different from that originally described, and he also held that if this was the plaintiff's invention it would not work without modifications and precautions which the plaintiff never pointed out. I agree with him on both points, and I will take the last first. It is, I think, clear that no one had ever shown or professed to show how to produce this desired effect before 1878. Many prior patents were referred to by the counsel for the defendants to show want of novelty in the plaintiff's invention; but there is no trace in any of them of any method of keeping the electromotive force in a main constant at any particular voltage, nor was that the object of any of them. I dismiss them all with that short observation. I pass from the novelty to the utility of the alleged invention, and to the sufficiency of the specification for carrying it out. The utility of the alleged invention depends not on whether by following the directions in the complete specification all the results now necessary for commercial success can be obtained; but on whether by such directions the effects which the patentee professed to produce could be produced, and on the practical utility of these effects. Can it be said that the invention, as described in the amended specification, was in 1878 a practically useful addition to the then stock of invention? To judge of utility the directions in the amended specification must be followed, and if the result is that the object sought to be attained by the patentee can be attained, and is practically useful at the time when the patent is granted, the test of utility is satisfied. Utility is often a question of degree, and always has reference to some object. Useful for what? is a question which must be always asked. The answer must be—useful for the purposes indicated by the patentee (*see* per Tindal, L.C.J., in "Cornish *v.* Keene" (1 Webb's Patent Cases); "Edison *v.* Holland" (6 Patent Cases, 243); and "Badische Anilin und Soda Fabrik *v.* Levinstein" (12 Appeal Cases, pages 712, 719, 720). An invention may be useful as indicating the direction in which further progress is to be expected, and yet that same invention may be useless for any other purpose; useless, that is, as an invention without further developments and improvements which have not occurred to the patentee. This is, in my opinion, the real truth with respect to the plaintiff's invention, as now claimed by him. He made a distinct and important step in advance. The plaintiff was the pioneer; he showed others the road to be followed, but he did not give the traveller the information necessary to enable him to travel on it. There were difficulties to be overcome which the patentee did not foresee, and against which he naturally made no provision.

There is an enormous mass of conflicting evidence upon the possibility of obtaining practically useful results by following the directions contained in his specification. Much of the evidence adduced against the patentee merely goes to show that by following the directions in the specification you cannot produce such good results as are produced by the defendants. This is obviously wholly immaterial. But there is besides a great deal of evidence to show that an electrician of ordinary skill could not have produced any useful result in 1878 if he simply followed the directions contained in the specification as amended with such variations only as an electrician of ordinary skill would have known how to make in 1878. So much more can be done now by a Planté battery than was suspected in 1878 that I have found the greatest difficulty in coming to a conclusion on this all important question; and I much regret that we have not had the assistance of an expert in electrical science to assist us. I have studied the whole evidence with all the care I can bestow upon it, and I have come to the conclusion that the plaintiff had not in 1878 invented what he now says he had, viz., a practicable method of keeping the electromotive force in the mains constant at about 100 volts by means of secondary batteries and dynamos used simultaneously, as described. The evidence adduced by the plaintiff shows that something like his invention can be worked on a small scale, and to a limited extent, when it is not necessary to charge the mains so as to produce a high-pressure when the lamps are connected with the main. Prof. Barrett's evidence as to what he did in his own laboratory for six years shows this; and it must be borne in mind that for a time he used water pipes and the earth as a return conductor, and showed them to be sufficient. But his voltage was low; his dynamo produced a current at a tension sufficient for his lamps without the aid of secondary batteries, and he used his batteries as reservoirs rather than as regulators. Moreover, Prof. Barrett did not produce those results earlier than six or seven years ago, when much more was known about what could be done with Planté batteries than was known in 1878. The other cases in which the plaintiff endeavoured to prove that his invention had practically succeeded will be found to have involved considerable important departures from his invention as described. The installation for Lady Conyers' ball is the best case the plaintiff has; but there the batteries were taken charged, which is a very important matter. The defendants have, in my opinion, succeeded in proving that the lamps will be destroyed if, whilst they are connected with the main, the batteries are charged at a sufficient voltage to work for any useful purpose. This objection to the patent goes to the root of the plaintiff's alleged invention. The objection is said by the plaintiff to be based upon the erroneous assumption that the batteries must be charged and emptied to an extreme extent. Charging and discharging are no doubt relative terms to be understood within reasonable limits; and a workman intelligent enough to seize the idea of the patentee would perhaps know in a general way that the electromotive power could be regulated and kept approximately constant without excessive charging or discharging, and the brightness or dimness of the lamps would be his guide. But conceding this I think it proved that high charging is necessary to keep the electromotive force constant, and at anything like 100 volts; and if necessary it is not disputed that the lamps will be destroyed if the batteries are charged when the lamps are on, unless precautions against this cause of failure are taken. None, however, are indicated in the specification. I think it proved that a small variation in pressure in the main will cause a current to go into or come out of the secondary battery for a very short time. But this is not enough for practical purposes. High charging being necessary, it is in my opinion proved that the plaintiff's invention will not work without switches; and these are not mentioned in the specification. Upon this point there is much conflicting evidence, attributable in great part at all events to the ambiguity of the term "switching." It was known before Planté invented his secondary batteries that the voltage of primary batteries could be increased or diminished by increasing or diminishing the number of cells. The mechanical means of doing this is called switching; and Planté himself pointed out that the voltage of his secondary batteries could be increased or diminished by similar means. Regulation to some extent takes place without switches. It is admitted by the defendants' own witnesses that the batteries have a steadying effect for a short time; that they act as regulators to some small extent, and Prof. Barrett has produced satisfactory results in his laboratory with low voltage without switches. In Lady Conyers' case there were no switches, but there was no dynamo at work. On the other hand, the evidence convinces me that for practical lighting with an electromotive force of about 100 volts, and with dynamos and batteries and lamps all in use, switching is essential, and that no ordinary competent electrician would have known in 1878 how to keep the electromotive power in mains constant at about 100 volts without further instructions than the plaintiff gave him.

The plaintiff's claim to have invented in 1878 a practically useful method of keeping the electromotive force in the mains constant at about 100 volts whilst the dynamos are running and the batteries are being charged and the lamps are on, cannot, in my opinion, be sustained. This is the broad ground on which I think the patent, as amended, must be invalid, and this was the only ground on which Lord Justice Smith condemned it on its merits.

Having arrived at this conclusion, it is unnecessary to consider the objections taken to the specification, upon the ground that the directions about the earth were misleading, and that the direction that the cells of the batteries should have very large conducting plates was too indefinite. I have hitherto made no allusion to the plaintiff's regulator; but this was, in my opinion, an essential part of his original invention. He says in his

Digitized by Google

original specifications that it is necessary—for what? The context shows that it was necessary to keep the electromotive force in the mains constant. This was a mistake, and the regulator and all that was said about it has been disclaimed and struck out by the amendment. But the effect of this is entirely to change the value of the invention as described in 1878, and to enlarge it, which was not permissible. (See "Gaulard and Gibbs," Patent Cases, 215.) In the original specifications the plaintiff drew a marked distinction between storing and regulating; the secondary batteries were for storing, the regulator was for regulating. It is true that storing involves of necessity a certain amount of regulation; but over and above such regulation as is necessarily incidental to storing, further regulation was said by the inventor in 1878 to be necessary for his invention. Between 1878 and 1883 he discovered that the regulator was not wanted, and that everything cou'd be done by secondary batteries as used in 1883, by which time dynamos and switching had been greatly improved. He accordingly disclaimed the regulator. I am satisfied that the plaintiff had no idea that he could do without the regulator when he obtained his patent. He learned it afterwards; and by disclaiming the regulator and amending his specification in 1883 as he did, the plaintiff essentially changed the nature of his invention for keeping the electromotive force in the mains constant. The claim to the use of the batteries as reservoirs had a definite meaning in the original specification, but it has a different and much wider meaning in the specification as amended in 1883. The plaintiff is now really claiming a patent for the mere use of Planté's batteries in conjunction with dynamos. Such a patent would not have been valid unless the patentee had done something more; he must have shown how the two were to be successfully worked together. Assuming that a patent for such an invention might have been obtained, the plaintiff's patent was not granted for any such invention. The effect, therefore, of the disclaimer and amendment made in 1883 has been to destroy the validity of the plaintiff's patent, if it ever could have been made to work. Upon this point, again, I agree with Lord Justice Smith.

It is needless to consider the question of infringement. I will only add that if plaintiff's patent could be upheld as a patent for the use of secondary batteries in combination with dynamos, then the defendants would obviously have infringed his patent. But unless his patent can be upheld to this extent no infringement has taken place. Convinced as I am that the plaintiff made a great step in advance when he suggested the application of Planté's batteries for the purposes of incandescent electric lighting, I feel bound to hold his patent invalid on the ground that it was granted for an invention very different from that which he now claims to be protected: and on the ground that it was not in 1878 useful for the main purpose for which it was invented, viz., the practical lighting of large districts; and upon the ground that his specification was insufficient to enable an electrician of ordinary competence and skill to carry it out without further experiments and invention as distinguished from more practice and increased dexterity and skill. The appeal therefore must be dismissed, with costs in the usual way.

LORD JUSTICE LOPES concurred.

LORD JUSTICE KAY: This action is brought to restrain infringement of the plaintiff's patent, and for an account of profits or damages. The patent is dated 1878, and has been amended by two disclaimers in 1882 and 1883. The case is one of some difficulty, and the difficulty arises in great measure from the fact that the patent relates to electric lighting by incandescence, and in 1878 no practical mode of doing this had been perfected. Mr. Lane Fox contemplated lamps in which the incandescent material was platinum or iridium, which was to be maintained at a luminous heat not *in vacuo*. The incandescent lamp now in use in which the material is carbon enclosed in a glass bulb exhausted of air was not brought into practical use until some years after Mr. Edison's patent in 1881. The real object of this action is to claim the exclusive right to the use of what are called accumulators in the modern system of electric lighting. I understand that accumulators are, in fact, what were originally called secondary batteries. They were invented or improved by Planté, and at the time of this patent were known as Planté's batteries. They are not batteries for the original generation of electricity; but if I rightly understand the evidence they are constructed of plates of lead partly immersed in dilute sulphuric acid, the alternate ones connected with the positive and negative poles of the battery and in the circuit with a dynamo or other generator of an electric current. When electricity is by the action of such generator passed through the battery, an alteration takes place in the bed-plates by the deposit upon their surfaces of peroxide of lead. When the generator ceases to act, if the circuit is continued there is a resolution of that peroxide, and the battery during that chemical process gives out a considerable quantity of electricity. Directly the generator ceases to act, however, the electromotive force—called otherwise the voltage or potential, lowers at first rapidly, and then much more slowly, and the current is maintained at this lower voltage for a considerable period, varying, of course, with the size of the plates in the battery, and the quantity in amperes of the charge. Although this was known before the plaintiff's patent, and Planté's batteries are accordingly mentioned in his provisional specification as "reservoirs" of electricity, the provisional specification does not indicate distinctly that they were intended in his combination to answer any other purpose. The combination which he claims that the defendants are infringing consisted of several elements: (1) A number of incandescent lamps arranged, not in series, but what is very inartistically called in parallel, that is through each of which passes not the whole current carried by the main wire, but a portion only drawn from the main wire by a small wire serving the lamp, from which it is returned also by a separate return wire; (2) the introduction into this system of several Planté batteries joined in like manner to the main wire at different points, and each having a separate junction with the return. The complete specification contains this sentence:—"In order to keep the electromotive force in the mains constant it is desirable to have, in the first place, several generating machines, also a number of reservoir batteries, as before explained." In the provisional specification the last clause of that sentence, "also a number of reservoir batteries, as before explained," did not occur. Instead, the sentence ran thus:—"Next it is necessary to have some regulator, such as that about to be described." The regulator was an electrometer, the needle of which oscillated between two metal points. When the voltage was too high it touched one, and completed a circuit which actuated a lever so as to shut off steam, and this diminished the speed of the dynamo. When the voltage got too low, the needle deflecting in the opposite direction touched another metal point, which produced the contrary effect and quickened the motion of the dynamo. This regulator is struck out by disclaimer, and now in the altered specification the only regulation is keeping the electromotive force in the mains constant, which is to be done by—(1) Several generating machines, and (2) a number of reservoir batteries. I find it impossible to make the provisional and complete specifications consistent in this respect. The provisional describes the mode of keeping the electromotive force constant, (1) several generating machines, and (2) the electrometer regulator. It does not mention the secondary batteries as useful for that purpose, but as reservoirs only. Mr. Lane Fox argued before us that their purpose was to act as a sort of buffer (to use the expression he frequently employed); and, accepting an illustration suggested by the Bench, he said their office was something like that of the air vessel in a force-pump, which arrests the pulsation of the pump, and causes the water to be delivered in a continuous stream. I am satisfied by the evidence that this would not be the effect of the secondary batteries if employed as described by his patent. He directs them to be charged from the dynamo while some lamps are in the circuit. Taking the voltage requisite for the lamps at 100, I think it is clear that the batteries, at least with any reasonable size of lead plates, could not be charged so as to be useful for this purpose with a current of less than 115 to 125 volts, which would destroy the lamps in a short time. Even if properly charged they could not practically be used to keep up the current when the dynamo was not running without an arrangement by which the number of battery cells in connection with the main wire could be altered from time to time by a system of switches. If the use of the batteries was to keep the electromotive force constant in the main wires there are two objections to this patent, each of which seems to me formidable. First, this is not contemplated by the provisional specification, which describes a different mode of effecting that purpose, and, therefore, differs essentially from the complete specification; and secondly, the mode of using the batteries described in the complete specification of this patent will not produce the effect of keeping the electromotive force constant in the main wire. The use of these batteries as reservoirs of electricity was merely using them for the purpose for which they were invented by Planté, and a patent for putting such reservoirs in connection with the main wires in a system of electric lighting involves no invention whatever, any more than using water reservoirs in connection with pipes supplying a city with water. By disclaimer the plaintiff struck out from his specification the regulation by the electrometer. As I read the provisional specification, this, and the employment of several generating machines, was the only mode of regulation which the patentee originally contemplated. But I think by regulation he did not mean keeping the electromotive force as nearly as possible constant in the various wires. The disclaimer has struck out one device for effecting this which is said both in the provisional and complete specification to be "necessary;" and it may be a question whether this is not an alteration of the invention which makes the combination now claimed essentially different. But the most serious objections in the view of this patent which I take is that it is a crude description of an invention which, as described, had no practical utility. Not one of the elements of the combination was new in itself. I am satisfied, as I have said, that the combination, as described by the patentee, could not be efficiently worked without at least two essential alterations—one, that the secondary batteries must be charged when the lamps were not in the circuit with a current of electricity of a voltage which the lamps would not bear; and, secondly, that these batteries would be practically useless unless they were worked with switches, as I have before mentioned. Without such an arrangement they could not be made to keep the electromotive force constant in the main wires. The automatic action which Lane Fox supposed would accomplish this is, I am persuaded, a mere delusion. These two essential alterations were necessary to make accumulators of use. Neither of them is contemplated by Lane Fox. Assuming that he was the first to suggest the placing of reservoir batteries in communication with the main wires in a system of electric lighting by branches from the main, his mode of doing this was practically useless, and for this reason I agree with the result at which the learned Judge has arrived. I think the patent is invalid, and that this appeal should be dismissed.

Appeal dismissed accordingly, with costs.

Northern Electric Wire and Cable Manufacturing Company (Limited) v. Fowler, Lancaster, and Co. (Limited).

In the Crown Court, Leeds, before Mr. Justice Grantham, on Monday and Tuesday last, this action was heard. The plaintiffs sought to recover £66, alleged to be due for cables, wire drums, &c., supplied. The defence was that there had been an overcharge in respect of some of the goods, and that certain allowances which should have been made for returns had not been made. The defendants also claimed £900 as damages for non-supply of electric cables within a reasonable time, whereby it was said the defendants suffered delay in completing the system of electric lighting on three battleships, and suffered by reason of not obtaining further contracts.

After a lengthy hearing his LORDSHIP, after commenting very strongly upon some of the facts given in evidence, and censuring both parties, gave a verdict for the plaintiffs for £39. 11s., and for the defendants for £58. 15s. 3d., without costs to either party.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July* 29, 1892.

Extensive Transmission Plant.—Although we do not hear so much about the installation of extensive plants for the transmission of power by electric means as we did six months ago, nevertheless there is going on a great deal of work in the preparation for some very elaborate installations of this character. I have it on the authority of the designing engineer of one of the large companies that he is preparing estimates for a plant for the transmission of power of 20,000 H.P. capacity. It is a fact that large installations are now becoming so common that their economy is better known to financial men than it was a few years ago, and these men are now making inquiries of the large companies for estimates on plants of from 5,000 to 10,000 and 15,000 H.P. capacity.

From Niagara Falls to Chicago.—Very little is heard now of the proposed installation of a transmission plant between Niagara Falls and Chicago. The idea of this plant of course originated with the successful operation of the Frankfort-Lauffen plant; but the distance in this case is so much greater than in the Frankfort plant that it is doubtful if any American or foreign firm cares to undertake the installation of the line, to say nothing of the experimental dynamo and motor plant.

Transformers in Long-Distance Transmission.—Foreign engineers, who, as a rule, are in favour of the use of step-down and step-up transformers in transmission of power plants, will be interested to know that there is considerable opposition to this plan among leading engineers in this country. American engineers are more in favour of the extensive use of copper in line construction rather than the expenditure of the same or even a less amount of capital in the installation of extensive transformers, which, however economical, would at best be more likely to break down, and cost more to operate and keep in repair than a good substantial copper line. American engineers do not place much confidence in the expectation that step-up and step-down transformers will come into use for plants where power is transmitted over less than ten miles, and some go so far as to express the belief that the direct method is much to be preferred for distances that do not exceed 20 miles.

The General Electric Company is rapidly carrying out the policy which has for many years prevailed in the management of the Thomson-Houston Electric Company under the direction of Mr. C. A. Coffin. The management cares very little for sentiment, and is planning to pay dividends to the stockholders rather than to make an extensive showing before the general public. The way in which expenses are being cut down is well illustrated by a step which has just been taken, which, although not expected by the stockholders of the former Edison Company, is characteristic of the management of the new Company. It is announced on good authority that the private laboratory of Mr. Edison has been quietly placed on the shelf as an expensive and unnecessary luxury, which the Company could not afford to keep up. Some 300 *employés* of Mr. Edison's laboratory who had been on the pay roll of the Edison Company have been discharged, and only enough *employés* retained to carry on what the Company consider the necessary experimental work of the laboratory directly in line with the apparatus which the Company is handling. A good authority states that the Company will save not less than $500,000 a year by this method; and the same authority states that another $500,000 has been saved by the entire abolition of what was known as the engineering and designing department of the Edison Works at Schenectady. Considering that, it is thought that it will not be very long before the stock of the General Electric Company is selling at a figure not far from 150, and that dividends will be increased to a considerable extent.

Lamp Manufacturing Companies are beginning to look with anxiety for a decision in the Edison filament patent case, although the general expectation is that it will be decided in favour of the Edison Company. It is more than probable that should the case be decided in favour of that Company, the General Electric Company will use the embarrassing position in which the Westinghouse Company will then be placed to force it to come into the combination at a very low figure, while the smaller companies will be either closed out or compelled to surrender their stock at a low estimate, depending on whether they have patents which the General Electric Company cares for; or whether, as is the case in a few instances, the smaller company holds one or two lamp patents which might later prove of value to the big Company. It is of considerable interest to know that the Sawyer-Man treating patent held by the Westinghouse Company is considered of sufficient value to warrant the taking in of the Westinghouse Company as a part of the consolidated Company.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS INVITED.—The Oldham Corporation invite tenders for the supply of switchboard instruments and connections. Specifications and drawings are to be obtained of Mr. Alex. B. W. Kennedy, 19, Little Queen-street, Westminster, S.W., and tenders must reach Mr. A. Nicholson, the Town Clerk, not later than Friday, the 2nd prox. Further particulars appear in our advertisement columns.

——— The Gas Committee of the Manchester Corporation invite tenders for the supply of an electrical crane at their station in Dickinson-street. General conditions of contract and specifications can be obtained on application (in writing only) to Mr. C. Nickson, Superintendent of the Gas Department, Town Hall; and tenders must be in by 10 a.m. on the 19th inst.

——— The Burnley Town Council invite tenders for various work required to be done in the erection of an electric lighting station in Aqueduct-street. Particulars may be obtained at the office of the Borough Surveyor; tenders must be in by the 30th inst.

——— The General Post Office invite tenders for the supply of hard-grown larch telegraph poles. Forms of tender, containing all particulars, may be obtained on application to Mr. Chas. E. Stuart, Controller of Stores, Telegraph-street, London, E.C., by whom tenders will be received until noon on the 22nd inst.

——— The Directors of the Baden State Railways invite tenders, to be delivered at Carlsruhe by September 5, for the lighting by electricity of their steamships "Kaiser Wilhelm" and "Grief." The Directors will also receive tenders until 31st October for the lighting by electricity of the central goods railway station and wharf buildings at Mannheim.

——— The Municipality of Alcañiz, Spain, invite tenders for the supply of an electric light installation for the town, and for the working rights for ten years. Particulars may be obtained from El Ayuntamiento Constitutional, Alcañiz, and tenders are to be in by the 30th inst.

——— The Municipality of Villena, Spain, invite tenders for the supply of an electric light installation for the town, with sole concession for fifty years. Particulars are to be obtained from El Ayuntamiento Constitutional, Villena, and tenders are to be in by Sept. 6.

TENDERS ACCEPTED.—The following tenders have been accepted by the Glasgow Corporation for the street lighting of the city:—

Engines...	Messrs. Easton and Anderson (Limited)	£1,108	0	0
Dynamos.	Brush Electrical Engineering Co. (Ltd.)	1,510	0	0
Arc Lamps	Ditto.	ditto.	7	13	8

——— The tender of Messrs. Cox-Walkers has been accepted for the supply of electrical tell-tale clocks for the Derby Borough Asylum, at £71.

TENDERS RECEIVED.—The following is the complete list of tenders for the supply of condensers for the electric light installation at Bristol:—

John Kirkaldy (Limited)	£6,042
Pulsometer Engineering Company (Limited)	5,965
Messrs. G. E. Belliss and Co.	4,960
Brush Electrical Engineering Company (Limited)	3,977
Woodhouse and Rawson United (Limited)	3,752

Digitized by Google

Part of the work specified in the latter tender, amounting to £50, was afterwards withdrawn, reducing the tender to £3,702, at which it was accepted, as previously announced.

MESSRS. JOHNSON AND PHILLIPS.—This firm have entered into a contract with the Chatham, Rochester, and District Electric Lighting Company (Limited), for the laying of underground mains at Chatham on the Brooks' oil system.

THE ELECTRIC LIGHT IN SPAIN.—The Allgemeine Elektricitäts Gesellschaft have obtained the concession for the installation of 800 16-c.p. lamps at the Casas Consistoriales at Barcelona, and for the erection of a central station at Oviedo; they are also making progress with the central station at Santander. The lowest tenders for establishing a central station at Tolosa were from MM. Manterola, and Planas, Flaquer and Co. The central station at Alicante, installed by Messrs. Siemens and Halske, has just commenced working.

ACCRINGTON.—At the last meeting of the Town Council a motion was adopted, calling upon the Legal and Parliamentary Committee to submit to the next meeting a full report with respect to the establishment of the electric light. In the course of the discussion it was stated that a number of local gentlemen were prepared to take up the matter of lighting the town, and the Mayor stated that the Council were only waiting for the erection of destructors in order to get power.

BILSTON.—The new Market Hall, which was opened on the 9th inst., is dependent upon electricity for lighting. The interior is lighted by eight 2,000 c.p. arc lights, and by 74 incandescent lamps of 16 c.p. in the closed stalls, offices, &c., and the exterior by two 2,000 c.p. arc lamps. The whole of the plant has been supplied and erected by the Brush Electrical Engineering Company (Limited).

BISHOP STORTFORD.—The Provisional Order granted to the Bishop Stortford Electric Light and Steam Laundry Company (Limited) has been revoked by the Board of Trade.

CARDIFF.—At the meeting of the Lighting Committee of the Corporation on Thursday (last week), Mr. Massey was appointed to carry out the electric light installation, to prepare plans, specifications and estimates, and generally supervise the work.

HECKMONDWIKE.—At the next meeting of the Local Board a resolution will be proposed to authorise the construction of the necessary plant for lighting Heckmondwike by electricity.

WALSALL.—At the last meeting of the Town Council the General Purposes Committee announced that 28 tenders had been received for lighting part of the borough by electricity, the tenders ranging from £6,712 to £22,733. The Electric Lighting Sub-Committee had been authorised to visit several towns in order to gather information respecting the systems of lighting adopted, and the success, or otherwise, of the installations.

WATERFORD.—The Corporation, having failed to come to terms with the City of Waterford Electric Supply Company (Limited) and with the Gas Company, have decided to light the city by oil lamps.

UNITED ASBESTOS COMPANY (LIMITED).—The Lords of the Admiralty have again awarded this Company the contract for the supply of all asbestos goods required in the Royal Navy during the ensuing twelve months, the principal articles being "Victor" block packing, "Victor" metallic packing, and hard-spun yarn packing for glands; "Victor" metallic sheeting, tape, rings, ovals, &c., for steam and hydraulic joints; asbestos millboard, asbestos tape, covering for steam pipes, &c.

EXHIBITION.—At the forthcoming Exhibition to be held in connection with the Royal Cornwall Polytechnic Society a feature is to be made of the application of electricity to the practical development of Cornish mining and quarrying, in lighting, pumping, hauling and ventilating. The Society offers a special medal for an electric rock drill.

ELECTRICAL TARGETS.—A Mr. W. H. Elton, of Exmouth, has recently taken out a patent for a new target to be worked by means of the electric current.

Mr. T. HARDING CHURTON.—Mr. Churton has secured the contract for lighting by electricity the new Police Buildings, including two Courts now being built, at South Shields.

MESSRS. EVANS, STEWART, PALMER AND CO.—This firm have secured the contract for an electric light installation at Messrs. Westley Richards and Co.'s premises, New Bond-street, W.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1892.—The tenth annual edition of the above well-known annual is on sale, price 7s. 6d.; post free, in the United Kingdom, 8s. 3d.; abroad (a few countries excepted), post free, 8s. 10d. A digest of the contents will be sent on application.

COMPANIES' MEETINGS & REPORTS.

City and South London Railway Company.

The ordinary general meeting of this Company was held on the 5th inst., at Winchester House, Old Broad-street; Mr. C. G. Mott in the chair.

The SECRETARY (Mr. W. F. Knight) having read the notice calling the meeting,

The CHAIRMAN said: Gentlemen, I presume that, as you have all had a copy of the report, I may assume that you will take it as read. If so, it becomes my duty to move:

"That the report and accounts as presented to the meeting be received and adopted."

It is satisfactory that during the past half-year the steady increase of traffic has continued, and that the position of the Company has decidedly improved. In the first place, the number of passengers has increased from 2,412,000 in 1890 to 2,813,000 in the last half-year. That shows an increase of about 400,000 passengers; but in addition to that we have, in the past half-year, the season ticket-holders, which are estimated to amount to 100,000 additional. Therefore, in round numbers, we may say that there has been an increase during the half-year of about half a million of passengers over the corresponding period last year. When you consider that last year was the first half-year of the opening of the line, and that there was naturally a very large rush of people who came to see the line simply from curiosity, and not from any intention to use it regularly, and also that during that half-year we had the large omnibus strike in London, which added to the receipts of the Company at the time, it is satisfactory to think that we have not only carried the half million additional passengers, but that we have carried them in excess of those artificial sources of receipts. Now, the progress of the line is not simply in connection with the increase of the passengers. We have increased receipts from other sources in the shape of rents and other small items, and we have the satisfactory fact that our expenses have decreased. The percentage of expenses in the first half-year amounted to 79 per cent. of the receipts, in the second half-year they were reduced to 76 per cent., and in the half-year just closed they have been further reduced to 70 per cent. I hope that figure will go on steadily decreasing half-year by half-year until we come down to a really satisfactory figure. Of course, in the early history of a small concern like this, the percentage of expenses must always be great, but as the traffic develops that percentage steadily decreases, as has been the case in the past history of almost all our English railways. You therefore see that during the three half-years of which we have had experience we have steadily increased our receipts half-year by half-year, and have steadily decreased our expenditure. In the first half-year the net earnings of the line were sufficient to pay its expenses and the whole of our debenture interest; in the second half-year they were sufficient to pay the expenses, the debenture interest, the full dividend on the preference shares, and to carry forward a moderate balance; in the last half-year they have been sufficient to pay the expenses, debenture interest, the full dividend on the preferred shares, half per cent. dividend on the ordinary share capital, and to carry forward a balance larger than we brought into the half-year. These are all symptoms of a very steady and satisfactory progress. I am sure we could all wish that that progress was more rapid, but at the same time we must recollect that all sound businesses have to be worked up by slow degrees, hard work, and good management. When, however, they have been so worked up they are far more permanent and solid than those successes which are achieved rapidly, and which too often rapidly diminish afterwards in the same way. I believe there is no better and no more permanent mode in which capital could be invested in this country than in a purely passenger line in the metropolis, if the cost of that line is commensurate with the probable income to be derived from it. I believe our costs in this line will be found in the future to be so commensurate, and that the future dividends, when they have steadily accumulated, as I believe they will, from half-year to half-year, will arrive at a figure that will satisfy all our shareholders. I will now call your attention to the accounts of the half-year in more detail. As regards the capital, we have issued £30,904 in preference shares and £3,300 in debentures, making a total of £84,204. We have received for surplus land sold £5.800, making the total receipts on capital account £40,004. That has cleared off a great many of the liabilities which were standing at the debit of capital account; but, as you will see, there is still a debt of £22,000 remaining there. We hope that in the course of this half-year we may be able to clear all that off, especially that portion which is now bearing interest. If you turn to the revenue account No. 9 you will see that the receipts from passengers and parcels amount to £20,940, and from rents and other small sources of income £580, making the total receipts £21,520 in the half year, against £19,637 in the corresponding half of last year, or an increase of £1,833. On the other hand, the expenses of maintenance have increased by the sum of £52, the locomotive expenses have decreased by £552, the carriage and waggon repairs have increased by £63, the traffic expenses have decreased by £484, the general charges have increased by £78, the law charges have increased by £35, the rates and taxes have increased by £250, and compensations by £134, making a total net decrease of £424. The result of the half-year's working is that there is a profit of £6,422 11s. 6d.,

Digitized by Google

against £4,116 in the corresponding half-year. This profit, added to £850 brought forward, in addition to the bankers' and general interest account, makes an available balance of £7,348. The debentures absorb £4,317, leaving £3,031 available for dividend. After paying the full dividend of 5 per cent. on the preference shares and ½ per cent. on the ordinary stock there will remain a balance of £983 to carry forward in place of the sum of £850 brought into the account of the previous half year. The amount to the credit of the profit and loss account would have been sufficient to pay a dividend of ¾ per cent. instead of ½ per cent., but we thought it much more in the interest of this Company that we should carry forward a larger balance and altogether be in a stronger financial position rather than pay the last penny comparatively that we had in the exchequer. One of the most interesting features in these accounts is always the question of our locomotive expenses. We still adhere to the word "locomotive" expenses, although they are not like the old locomotives. However, they are locomotives, though the force is electricity. In the first half-year our expenses were 9d. per train mile; in the second half-year they were reduced to 7·9d. per train mile; and this half-year, although there is no increase in the train mileage, the expenses are reduced to 7·7d. per train mile. In comparing these figures with those of an ordinary steam railway, you must, as I pointed out to you last half-year, recollect that we have, in addition to the work of an ordinary railway, the lifts and the hydraulic apparatus for taking the passengers to and from the surface down to the train. That makes a very considerable item in the cost of the working of our railway, and although it does not affect the locomotive expenses, it affects our general expenses to a considerable extent. But still, with all that, we are able, I think, to compare favourably upon all points with the ordinary steam railway in this country. As I told you, the locomotive expenses are 7·7d. per train mile. The ordinary locomotive expenses of the large English railways, when they get their coal at the pit's mouth without any carriage upon it, come out at the present moment at about 9d., or a trifle over, per train mile, Where they have to pay carriage upon it, as in the case of the lines South of the Thames, where there are no collieries on the lines, it is increased to 10d. or 10½d. per train mile. Of course, in our case we have not only to pay the carriage of the coal from the colliery, but we have also to pay the carriage from the station to the depôt. This increases the cost of our coal, which is a considerable item in the locomotive charges, considerably above that of any of the other railways; but, notwithstanding all these additional charges, you see that we stand at 7·7d. against 9d. to 10½d. per train mile. Of course, on the other side, our steam friends will tell us that our trains are not capable of carrying so much traffic. It is perfectly true; but, at the same time we are capable of carrying a very large traffic, and our number of passengers per train is slowly and steadily augmenting by every train we run. The average number in the first half-year was 45, in the next 46, and in the third 47 per train run. The question of fares is rather an interesting one. You remember we began with a uniform fare, which we found it necessary and expedient to alter from time to time to suit the exigencies of the traffic. The result was that in the first half-year, before we altered it to any extent, we received 1·90d. for each passenger; in the next half-year that was reduced to 1·70d. per passenger, and in the last half-year there has been a slight increase, it is 1·73d. per passenger. As far as we can judge, the result of the alterations has been satisfactory, because although we are actually earning less per passenger than we did in the corresponding period of last year, we have got a considerable increase in the total receipts. Now we will turn to the report. This being the only installation of the kind in this country, if not in the world, naturally there has been a great deal of interest to see our generating station, and in what way the power is produced. That was somewhat inconvenient to us because it interfered with the people employed at the works. We thought it, therefore, better to put up a small gallery in the engine house apart from the people employed, and to allow the public to have access to that gallery, where they could see the whole of our engines at work on payment of a small sum. I am glad to say that that has been approved generally, and that we have a steady number of people every day visiting that gallery, and adding something to the funds of the Company. Paragraph 6 of the report deals with the Joint Committee of both Houses of Parliament that was appointed to consider and report upon the best method of dealing with the various electric and cable schemes in the metropolis, proposed last Session for the sanction of Parliament. That Committee reported most favourably as regards those schemes, both as to construction and as to their working by electricity, and they have suggested that in future it would be desirable to give to any schemes easements under property where they did not do any damage at a small cost without the necessity, as we have had to do hitherto, of following the line of the streets. No doubt if this is approved by Parliament and carried out it will give much more direct and better lines than would otherwise be constructed, and diminish the cost of the extension of lines of this kind. Six years ago to-day no steps had been taken even to start the construction of this line. It is a little more than five years ago since the idea first entered my mind that we might work this railway by electricity in place of the cable system for which it was originally intended, and it seems extraordinary that in that short space of time such an entire revolution should have taken place in the views of people travelling in the metropolis that in five years' time we have applications for numbers of railways in the metropolis, and, strange to say, all of them proposed to be worked by electricity. Well, gentlemen, if the shareholders have not yet got an adequate return financially for their money, they at all events have the satisfaction of knowing that they have inaugurated a new system of locomotion, which is destined, I believe, to have a far reaching expansion and add to the comfort and prosperity of the inhabitants of this country very largely. You remember we introduced a Bill for extending our line to Islington and getting rid of the inclines under the river. That Bill was introduced into Parliament with the other Bills, but owing to the dissolution only two of these were actually passed. A Special Act was passed by which these Bills will not suffer through the dissolution, for they will be taken up this Session now at the stage they were left in. I do not, however, suppose anything further will be done with them until the early part of next year. During the past half-year we have been carefully consolidating our machinery at the generating station. We have got the new engines and the new dynamo at work, and we are now in a position to meet every possible contingency that is likely to happen on this line, and, further than that, to work a very large extension of the line without any material addition to our plant. We want as far as possible to meet the growing traffic by additional trains, but, as I have explained to you before, one of our difficulties is the want of siding accommodation. We had hoped to have gone on with that work during the past half-year, but it was delayed for various reasons. We hope within a few weeks now to start those works and sidings, which, when completed, will be of very great advantage to the working of the line. The next question which arises on paragraph 9 of the report is with reference to the debentures. Our debentures were first issued as terminable debentures. We felt at the time we issued them that it would be wrong to burden this line with a permanent 5 per cent., and I think we were wise in that decision. We therefore issued them for periods varying from five to ten years, and some of them will become due in the course of the next year. We propose to ask your sanction now for the creation of permanent debenture stock. Our idea is to issue that stock at the same rate as most of the companies have issued theirs; that is, as a Four per Cent. Stock, but of course the price of that stock at the time of its issue will determine the rate of interest which you will actually pay. We shall do our best to get it issued on the very best terms as regards premium, and we think it probable that a good many of the existing debenture-holders may, in view of the probability of that stock rising to a considerable premium, be disposed to convert their debentures upon terms to be arranged before they expire. In any case we shall be in a position to pay those off and supplement them with the debenture stock, the interest upon which will be not more than 4 per cent., and we hope something like 3½ per cent. or perhaps less. If the interest is reduced to 4 per cent. we shall save some £2,000 a year, or even £2,500, which is an important item in a small concern of this kind. After referring with great regret to the death of Mr. Kitson, a late auditor, he continued: I do not know that I have anything further to say beyond the fact that I look forward personally with great satisfaction and hope to the future of this line. I think if we all work together we shall be able to make it one of the most satisfactory railways, both financially and for comfort and convenience of the public that has ever been carried out in this country. The line as a Metropolitan line is certainly even at the present time unequalled. Its trains are run with great punctuality, at short intervals and in an atmosphere that is pure. The temperature is equable, and it is cool in summer and warm in winter. Our railway avoids all the fatigues of going up and down long flights of stairs, as in the case of most of the other Metropolitan railways, and altogether its comforts and conveniences are very great, while in the future they will, I believe, be very much greater, as gradually, by degrees, we improve all the small details of its workings. Our first endeavour naturally was to get rid of the frequent breakdowns that interfered very much with the traffic. I am happy to say they are now events of very rare occurrence, and I hope the time will come when they will be almost absolutely unheard of.

Mr. SAMPSON HANBURY seconded the resolution.

A short discussion followed, and the Board were asked what steps they proposed to take to develop the traffic, it being suggested that it was practically only in this direction that an improvement in the position of the Company could be looked for, the working expenses having been already brought to about as low a point as possible. The importance of running the trains at more frequent intervals was also advocated. The traffic existed, but it was pointed out that it could only be carried at certain hours.

The CHAIRMAN, in reply, stated that no question had absorbed the attention of the Directors so much as that connected with increasing the carrying capacity of the railway. A very considerable addition to the accommodation of the line had been given, but as long as they had been subject to frequent breakdowns, it was absolutely necessary that they should not attempt to carry more traffic than they could rightly deal with. It was of no use to increase the number of the trains only to augment the number of the stoppages. They had increased the number of the trains at certain hours of the day, when the traffic was busiest, and had reduced them at those periods when the demand for accommodation was less. The consequence was that, although the train mileage remained very much the same, the actual accommodation during the busy hours of the day had been very much increased. The one particular point to which they must direct their attention was giving the accommodation that was required, and they were now running more trains than ever. The shareholders had given the Board permission to deposit a Bill to get rid of the inclines in the river and to extend the railway into the City. He believed that if the Bill were carried through the Company would derive very great benefit. It would enable them to give such a service of trains as would command a very large increase of traffic, and the Company would be able to give this service at a very small additional expenditure. The overcrowding of the trains in the morning and evening, to which reference had been made, was not exceptional in the case of this Company; it was a feature in all trains coming into London from the suburbs.

The motion was then unanimously adopted, and the dividends on the preference and ordinary shares were afterwards declared, Mr. James L. Oliver being subsequently appointed an auditor in place of the late Major Kitson.

Resolutions were afterwards passed on the motion of the CHAIRMAN, authorising the creation and issue of the debenture stock and preference shares, as mentioned; and the meeting closed with a cordial vote of thanks to the Chairman, Directors, and staff of the Company.

Halifax and Bermuda Cable Company (Limited).

The third annual meeting of the shareholders was held on Monday, when the Directors' report and accounts were unanimously adopted, and the auditors were re-elected.

The following is the report of the Directors:—

The result of the working for the year ended June 30, 1892, is a profit of of £1,261. 14s. 2d., to which has to be added the balance brought forward from last year of £420. 5s. 5d., making the sum now to the credit of revenue £1,681. 19s. 7d. The cable receipts in the past year were £3,915. 13s. 3d., as compared with £4,018. 9s. 4d. in the preceding year. Notwithstanding this slight decrease the Directors regard the result as quite satisfactory, as in 1890-1 there were exceptional sources of traffic. At the same time the Directors have been able to effect further economies, so that the working expenses as shown in abstracts A. and B. are £609. 10s. 3d. below the totals of the previous year.

It is subject for congratulation that all the outstanding difficulties in connection with the foundation of the Company have been brought to a satisfactory conclusion. The claims of the Construction Company have been discharged, all open matters with the International Cable Company, (Limited), have been finally adjusted, and the very heavy legal charges have been met. The result of these adjustments is that £10,153. 16s. 10d. has been expended beyond the outlays chargeable to capital account. This has in part been met out of revenue account, but, to the extent of £6,000, money has been provided on advantageous conditions by the new friends of the Company.

The Company's cable has throughout the year worked with complete efficiency, and its present electrical condition is excellent.

Under the Articles of Association the two senior Directors should retire. These are Sir Alexander Armstrong, K.C.B., and L. H. Isaacs, Esq., but these gentlemen do not seek re-election, and on the ground of economy it is not proposed to at present fill the vacancies thus created. The auditors, Messrs. Gribbon, Ingram and Holroyd, retire in accordance with the Articles of Association, and they offer themselves for re-election.

Croydon Tramways Company.

At the ordinary general meeting of this Company on Tuesday, Mr. W. J. Carruthers-Wain in the chair, the report presented by the Directors stated that the experiment in connection with electric traction had given satisfactory results. They had earned £167 on 3,323 miles run, the payment to the Electric Tramcar Syndicate therefore being £81, and the number of passengers carried thereon had been 25,649.

In the course of his remarks in moving the adoption of the report, the CHAIRMAN reminded the shareholders that at the last meeting reference was made to the arrangement which had been entered into with the Electric Tramcar Syndicate. The arrangement was on a principle which he very much liked—namely, "Heads, I win; tails, I do not lose." They made a contract by which the Syndicate was to run a certain number of cars on the Company's line for a fixed figure per mile run. The result had been most satisfactory to the Company, and the Directors had found, as most tramway companies did, that the greater the facilities they gave to the public the greater their own advantage was. The new traction seemed to increase the traffic, because the public were first of all given a novelty, and then when they got tired of the novelty they found that this particular means of traction in itself was much more advantageous in enabling them to get about their work or pleasure than the old plan. He was very sorry that, from circumstances with which their Company had nothing to do, the Electric Tramcar Syndicate was not at present working the cars, but they hoped to be able to do so again, and it would be then for the Directors to see if another arrangement could not be made with them. He would like to see the whole of their system worked by electricity. In answer to questions he stated that the Syndicate was undergoing a process of domestic reconstruction, and he had not at present received a definite proposal from them. He had hoped to have received from them a suggestion which would have enabled him to give some satisfactory information to the shareholders on the point, but at the present moment the arrangements of the syndicate were not completed.

Cuba Submarine Telegraph Company (Limited).

The following is the report of the Directors to be presented at the forty-second ordinary general meeting of shareholders, to be held at 58, Old Broad street, E.C., on the 17th inst, at 12 noon:—

The gross receipts for the half-year ended June 30th last (including the balance brought from last account) amount to £24,537. 11s. 6d., and the gross expenditure (including the half of the annual payment on account of the 1881 cable) to £7,311. 6s. 5d., leaving a sum of £17,226. 5s. 1d. to the credit of revenue account.

There have been throughout the half-year no interruptions of any of the cables, and, therefore, no repairs have been required, so that the sum of £7,000 has become available for, and has been transferred to, the reserve fund.

The dividend on the Preference Shares will absorb £3,000, and leave £7,226. 5s. 1d., out of which the Directors recommend the payment of a dividend on the ordinary shares at the rate of 8 per cent. per annum, free of income-tax, the balance, £826. 5s. 1d., being carried forward to the current half-year's account.

By the decease in February last of Mr. Neil Bannatyne, the Company has lost the services of one of its first Directors, and one who was very active in its interests. On receiving an intimation from Mr. Keith—who had been Engineer and General Superintendent of the Company in Cuba for over fifteen years—that he desired to retire and remain in England, the Directors availed themselves of the opportunity to retain his valuable aid by electing him to the vacant seat at the Board. An arrangement has also been made to secure his services in the supervision and repair of the cables, upon terms both advantageous to the Company and agreeable to him. These terms will be submitted to the proprietors at the meeting.

The Company's suit against the Spanish Government at Madrid is progressing.

The Director who retires from the Board at this time is Mr. Charles W. Parish, who, being eligible, offers himself for re-election. Mr. John Gane, the auditor, also retires, and offers himself for re-election.

Telephone Company of Ireland (Limited).

The following is the Directors' report to be presented at the ordinary general meeting to be held at the offices of the Company, Dublin, on Thursday next, the 18th inst., at 12 noon:—

The Directors present their report and statement of accounts for the year ended December 31, 1891. A supplementary statement for the half-year ended June 30, 1892, is also presented, pursuant to Clause 56 of the Articles of Association, which requires that the accounts shall be made up to a date not more than four months before the annual meeting.

The Directors regret the delay that has occurred in the issue of the report, but the expiry of the two master patents in December, 1890, and July, 1891, rendered it desirable that all outstanding questions and accounts between this Company and the parent Company should, so far as possible, be finally disposed of, and that the accounts should be certified by the auditors of both Companies before being presented to the shareholders. Save as to a sum of £395. 18s. 5d., the accounts between the two Companies are now agreed to December 31, 1891, and are duly certified. In connection with this sum of £395. 18s. 5d., it should be explained that the parent Company claims to be entitled to royalty in respect of a third patent relative to the transmitters, expiring in January, 1893, and also to a rental for the telephone receivers, the patent for which expired in December, 1890. No agreement has yet been come to as to the correct amount to be allowed, but no doubt a settlement, satisfactory to both companies, will be arrived at, and failing such settlement the matter will be submitted to arbitration, in accordance with the terms of the licence. It is expected, however, that the total claim under these heads for the years 1891 and 1892, and until the date of the expiration of the third patent, January 30, 1893 (when all royalties other than those to the Post Office cease to be payable), will not exceed £650. On the expiration of the last patent, in respect of which the parent company claims royalty upon the instruments till January, 1893, it may become necessary to purchase from the National Company the whole of the telephones and transmitters now in use.

The business of the Company continues to show a steady development. The number of wires, exchange and private, under rental upon December 31, 1890, was 1,473. On December 31, 1891, the number was 1,538, being an increase of 65 for the year, notwithstanding the great interruption caused by the severe snow-storm of November, 1890, which paralysed the Company's business in Dublin during the early months of the year 1891. The increase in the number of the subscribers still continues, and, coupled with the reduced amount payable for instrument royalties, cannot fail to have a favourable effect upon the revenue for the current year, and a still more favourable effect in the ensuing year, when the instrument royalties will altogether cease.

It has been considered prudent to write off from the revenue of the year the whole of the expenses (£1,262. 3s, 2d.) connected with the issue of the debentures, and also the whole of the allowances (£672. 4s. 8d.) made to the Company's subscribers during the period when the system was under repair after the damage caused by the snow-storm in November, 1890, and also to write off on account of bad and doubtful debts a larger amount than usual, namely—£368. 11s. 10d., as compared with £181. 8s. 7d. for the previous year. Were it not for these very exceptional deductions the balance of gross revenue transferred to net revenue account would have been £5,821. 10s. 6d., instead of £3,699. 19s. 5d., as against £4,646. 14s. 11d. for the year ended December 31, 1890.

Out of the proceeds (£10,995) of the issue of £12,100 debentures made last year, a sum of £5,000 was paid to the parent Company on account of royalties and arrears. Of the balance (£5,995), £4,000 is invested in Dublin Corporation Three and a-Quarter per Cent. Stock. All expenditure upon capital account during the year, including the cost of erecting the trunk line to Belfast, has thus been practically borne by revenue.

For the information of the shareholders the Directors annexed to the report a copy of the Treasury minute upon the Government proposals for the development of the telephone system in the United Kingdom. The Bill to give effect to these proposals has received the Royal assent. The shareholders will perceive, from a careful perusal of the minute, that a new and important development of the Company's business is imminent, and it may become desirable for the Company either to acquire from the National Company their business in Ulster, or to amalgamate with that Company, the Directors being of opinion that the telephone business of Ireland would be better developed if placed under one control and management. All the telephone companies, subsidiary to the parent company, have now, with the exception of this Company, been absorbed by the National Company. In the event of an amalgamation being ultimately decided upon as preferable to a separate company for Ireland, the Directors will endeavour to effect it upon such terms as shall be just alike to this Company as to the National Company. The Post Office Department is authorised under the provisions of the Bill, to purchase from the telephone companies all trunk lines erected by them, and in these circumstances the Directors expect that the outlay under this head, which has

Digitized by Google

been considerable and largely made out of revenue, will be recouped, and the revenue account thus placed on a satisfactory footing.

Pending a final settlement with the National Company on the expiration of the patents, and a possible readjustment of the relations of this Company with them, and having regard to the probability of capital being immediately needed to meet developments, the Directors consider it prudent to keep a substantial cash balance available. The Directors do not, therefore, propose to pay the preference dividend, or any dividend on the ordinary shares at present, but the preference dividend being cumulative its payment is only postponed.

The balance standing to the credit of the net revenue account, as upon December 31, 1891, including the balance brought from last account, amounts to £5,362. 10s. 11d., which the Directors propose to allocate as follows:—To the credit of the reserve fund, £369. 19s. 10d. (being 10 per cent. of the net profits of the year), carrying forward the balance of £4,992 11s. 1d. to credit of the current year. An examination of the supplementary accounts to June 30, 1892, will show that the balance to credit of net revenue at that date is sufficient, not only to pay the whole of the preference dividend, but leave a substantial sum for division amongst the ordinary shareholders.

In conformity with the Articles of Association, one of the Directors, Mr. Arthur Dudgeon, retires at this meeting, but is eligible for re-election. The auditor, Mr. John M. Kean, also retires at this meeting, but is eligible for re-election.

Liverpool Overhead Railway Company.

The following is the report of the Directors, to be submitted to the eighth half-yearly general meeting of the shareholders to be held at the Law Association Rooms, 14, Cook-street, Liverpool, on Tuesday next, the 16th inst., at 3 p.m.:—

Your Directors have to report that fair progress has been made during the past six months with the construction of the railway, and only 61 spans of the main structure are now required to complete. The permanent way is laid as far as the viaduct is finished. The electrical generating station is far advanced, and the engines are in course of erection. It is hoped that the railway will be completed in October.

The amount expended in construction during the past six months is £105,368. 16s. 8d. The balance to the credit of revenue account at the end of last half-year was £913. 7s. 11d., to this must be added receipts for interest and transfer fees £358. 11s. 8d., and after deducting interest on amount paid in advance of calls £60. 11s. 1d., and administration expenses £491. 7s. 1d., a balance is left to the credit of net revenue account of £720. 1s. 5d.

Your Directors have obtained an Act of Parliament providing *inter alia* for an extension of time for completing the railway, and authorising the construction of certain extensions at the north and south ends of the railway.

NEW COMPANIES, STATUTORY RETURNS, &c.

CAPON, HEATON AND CO. (LIMITED).—This Company was registered on the 5th inst., with a capital of £20,000, in £10 shares, to carry on the business of manufacturers of and dealers in india-rubber, gutta-percha, and other elastic substances, at Lifford's Mill, King's Norton, Worcestershire.

JONAS AND COLVER (LIMITED).—This Company was registered on August 6th, with a capital of £125,000, in £50 shares, to carry on the business of steel manufacturers and merchants, mechanical and electrical engineers, iron founders, &c., carried on by Joseph Jonas, at the Continental Steel Works, Attercliffe, Sheffield.

COLVER BROTHERS (LIMITED).—This Company was registered on August 6th, with a capital of £20,000, in £50 shares, to carry on the business of steel manufacturers, mechanical and electrical engineers, wire drawers, &c., at Pilot Works, Sheffield.

HOVE ELECTRIC LIGHTING COMPANY (LIMITED).—This Company was registered on August 4th, with a capital of £40,000, in £5 shares. The objects are to enter into and carry into effect agreements with the Hove Commissioners and Messrs. Crompton and Co. (Limited) to carry on the business of an electric lighting company in all its branches, within the district of the Hove Commissioners and elsewhere; to construct, lay down, establish, and carry out all necessary cables, wires, lines, accumulators, lamps, and works; and to carry on the business of electricians, mechanical and electrical engineers, iron, brass, and metal founders, suppliers of electricity for the purposes of light, heat, power, or otherwise, and of manufacturers of and dealers in all apparatus and things required for, or capable of being used in connection with the generation, distribution, supply, accumulation, and employment of electricity. The subscribers are:—

	Shares.
Harold A. Hoare, Lloyd's, E.C.	1
Colonel Alexander J. Filgate, 106, Jermyn-street, S.W.	1
Colonel Henry Wood, 95, Thorpe-road, Norwich	1
Carleton F. Tufnell, Lloyd's, E.C.	1
R. E. B. Crompton, Mansion House-buildings, E.C.	1
J. F. Albright, Mansion House-buildings, E.C.	1
Francis R. Reeves, Little Heath, Potter's Bar	1

The number of Directors is not to be less than three, nor more than five, the first to be nominated by the above-named signatories. Qualification, £500. Registered office: Mansion House-buildings, London, E.C.

LYNCH AND CO. (LIMITED).—This Company was registered on August 4th, with a capital of £25,000, in £1 shares, to carry on the business of manufacturers of electrical, chemical, photographic, surgical and scientific instruments and apparatus, at 192, Aldersgate-street, E.C.

UNITED ELECTRIC SEWAGE AND CHEMICAL SYNDICATE (LIMITED.)—This Company was registered on August 5th, with a capital of £5,000, in £1 shares. The objects are to acquire, work, develop, exercise and carry out the English, foreign and colonial rights of W. Walker, electrical engineer, of 132, Adelaide road, London, N.W., for and in his invention for which letters patent have been applied for (No. 14,039 of 1892), for "An improved process and apparatus for the purification of sewage and the production of alkalies, chlorine, ferric chloride and electric energy, and all improvements thereunder;" to carry on the business of electricians, suppliers of electricity, sewage engineers, manufacturers of chemicals for the purification of sewage, and manufacturers of and dealers in electrical and scientific apparatus.

CHILI TELEPHONE COMPANY (LIMITED).—The annual return of this Company, made up to July 22nd, has been filed. The nominal capital is £250,000, in £5 shares; 40,000 of these have been taken up, the full amounts called, and all calls (£200,000) paid.

EASTBOURNE ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of this Company, made up to July 4, 1892, has been filed. The Company was registered on February 15, 1882, with a capital of £50,000, in £10 shares. 1,017 ordinary and 47 deferred shares have been taken up, and the full amount and all calls (£10,570) paid.

ELECTRIC TRAMCAR SYNDICATE (LIMITED).—By a resolution passed on July 11th, and confirmed on July 27th, it was decided to wind up the Company voluntarily.

KENSINGTON COURT ELECTRIC LIGHTING COMPANY (LIMITED).—A resolution was passed and confirmed at meetings held on July 21st and August 5th, that the Company be wound up voluntarily, and that Mr. R. S. Erskine be the liquidator.

MANCHESTER EDISON-SWAN COMPANY (LIMITED).—The annual return of the above-named Company, made up to July 18, 1892, has been filed. The nominal capital is £550,000, divided into 50,000 "A" shares of £9 each and 10,000 "B" shares of £10 each. 20,000 "A" and 10,000 "B" shares have been taken up, £1 per share called on the former and the full amount on the latter class of shares, resulting in the payment of the full amount, viz., £120,000.

SHEFFIELD TELEPHONE, EXCHANGE, AND ELECTRIC LIGHT COMPANY (LIMITED).—A resolution was passed on July 18th, and confirmed on August 2nd:—"That it is expedient to reconstruct the Company, and accordingly that the Company be wound up; and that T. G. Shuttleworth, Sheffield, C.A., and Wm. Johnson, Sheffield, the secretary, be liquidators."

TELEGRAPH MANUFACTURING COMPANY (LIMITED).—The annual return of this Company, made up to July 29th, has been filed. The Company was registered on November 20, 1886, with a capital of £25,000, in £10 shares; and by special resolution, passed May 22, 1888, and confirmed June 7, 1888, the capital was raised to £50,000 by the creation of 2,500 new shares of £10 each. At the time of making up, 2,800 shares were taken up, of which 646 had been issued as fully paid. Upon the remaining shares the full amounts have been called, and all calls (£21,510) have been paid.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended Aug. 7th were £919, as against £822 for the corresponding period of last year, being an increase of £97. The total receipts for half-year amount to £4,703, against £4,299 in the corresponding period of 1891, being an increase of £404.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—Notice is given that the transfer books and register of members of the above Company will be closed from Thursday, the 18th inst., to Wednesday, the 31st inst., both days inclusive.

COMPAGNIE DE L'INDUSTRIE ELECTRIQUE GENEVOISE.—The accounts submitted to the recent general meeting of this Company showed a net profit for fifteen months' working of the Geneva Central Station, sale of apparatus, and the construction branch, of 130,709 francs, and a dividend of 5½ per cent. was declared. In order to consolidate its floating debt, and to provide for construction of new works, the Company have decided to issue Four and a-Half per Cent. Obligations to the amount of 800,000 francs.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this Company for July, 1892, amounted to £23,200; and from January 1st to July 31st to £152,000. In the corresponding months of 1891 and 1890 the amounts were £165,800 and £156,000 respectively.

MUNTZ'S METAL COMPANY (LIMITED).—The Directors notify an interim dividend for the half-year ended June 30th at the rate of 10 per cent. per annum, payable on the 1st prox.

WESTMINSTER ELECTRIC SUPPLY CORPORATION (LIMITED).—An interim dividend for the half-year ended 30th June last, at the rate of £3 per cent. per annum, has been declared. This dividend will be payable on the 15th September.

Digitized by Google

ONCKEN PATENT STAVELESS BARREL COMPANY (LIMITED).—The prospectus of this venture has been issued, and contains the statement that Mr P. Allen, late chief engineer to the Anglo-American Brush Electric Light Corporation (who is the engineer to the Company), and Messrs. Bonhoulle and Paun, engineers of Antwerp, have reported favourably on the advantages and efficiency of the electrical process owned by the Company for seasoning wood.

PIONEER TELEPHONE COMPANY (LIMITED).—Notice is given that an extraordinary general meeting of this Company will be held at Winchester House, E.C., on Tuesday, the 16th inst., at 2:30 p m., for the purpose of considering, and, if thought fit, passing the following resolution :—"That the Company be wound up voluntarily." Should the above resolution be passed by the required majority it will be submitted to a subsequent extraordinary general meeting for confirmation as a special resolution. The meeting will also be asked to pass a resolution fixing the amount to be paid to the Directors by way of remuneration for their services.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended Aug. 5, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,771.

WOODHOUSE AND RAWSON UNITED (LIMITED).—The Stock Exchange Committee appointed yesterday (Thursday) a settling day in the further issue of this Company's ordinary shares, Nos. 90,001 to 105,200, and preference shares No. 70,001 to 81,088.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 744.—Vol. XXIX. FRIDAY, AUGUST 19, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6.

NOTES.

In our issue of the 22nd July we published a letter which had been issued by the Secretary of the London Chamber of Commerce to the members of the Electrical Trade Section, inviting them to fall in with the suggestion of Mr. Preece with regard to the Chicago Exhibition, that a suite of rooms should be appropriately fitted up and lighted by electricity, so as to give some idea of the state of electrical engineering in this country. We now learn that not a single favourable response has been received to that circular. The electrical trade evidently agrees, as we anticipated it would, with the makers of steam engines, that there is nothing to be gained by exhibiting.

The outcome of the discussion on Electrical Standards at the British Association was the recognition by the representatives of Germany and France of the accuracy of the determinations which had been adopted by English electricians, who, in return, gave way upon the definition of the unit.

A delicate distinction has been drawn between a standard and a unit. As far as we understand it, the unit defines the standard, and the ohm as a unit is, in deference to continental wishes, to be a mercury column. This column is to be 106·3 centimetres long and of one square millimetre section. Most of our readers who have given this matter any attention are aware that in 1884 the length 106 was adopted at the Paris Conference, although there was strong evidence to show that 106·25 was nearer the true value. It was a fight, as Lord Kelvin said at the Leeds meeting, of 106 or nothing. Measurements have since been carried to a much greater degree of accuracy, and our continental friends have been obliged to admit the ·3.

The Weights and Measures Act is a marvellous affair, but we understand that the B.A. committee have succeeded in matching it by so wording their resolution that no one need trouble after all to measure his 106·3 centimetres, or, what is much more difficult, if indeed it is possible, to measure the internal sectional area of his tube; for he will be provided with a standard, and this will be a metal wire, or rather a number of coils between which comparisons will be made, as Mr. Glazebrook has continually done with the B.A. and other coils under his charge. The report of the committee should be considered with the discussion which followed, and with the arguments which led to it; and we therefore postpone its publication until next week, when we hope to give it in full, together with these necessary additions.

The delay in the issue of certificates for approved patterns of electric supply meters by the Board of Trade has not been due to want of completion of the Laboratory of the Electrical Standards Department, or to any shortcomings of the staff, but is clearly explained by the letter from Sir Courtenay Boyle which will be found in another column. The Shallenberger meter alone has received approval for certain Provisional Orders, and of course for alternating currents only; but this approval, it is explicitly stated, will not at present be further extended. With this exception, no meter whatever has yet been certified by the Board of Trade; and although two meters of the motor type passed the laboratory tests with a sufficient degree of success to satisfy the required conditions, reports of the behaviour of these instruments in regular work have, we believe, made it necessary to postpone the issue of certificates for the present, and it is evident that the "thorough practical test" which is referred to is something more than the careful scientific examinations which have hitherto been made.

It would doubtless have been possible to have issued provisional certificates, and at first sight this would appear to be a convenience both for the consumer and for the supply company, but such a course would really benefit only the meter-makers, for it would encourage the supply of meters which might afterwards have to be abandoned. As the certificates of the Board of Trade approve of a type of meter, and not individual instruments, the whole of these meters would have to be remodelled if, indeed, they were not placed, patents and all, *hors de combat*.

The examination of electric supply meters has been most carefully conducted, not so much to test the degree of accuracy of the specimens which were submitted to the Board of Trade, but to prove the proportionality of their readings to the current or energy sent through them, both under ordinary conditions, and at different temperatures and atmospheric pressures. It is rather fortunate that these examinations were carried on with some deliberation, since far less scientific but very important tests were being conducted elsewhere on a

Digitized by Google

large scale—that is to say, many hundreds were in daily use; and the behaviour of these, rather than of the meters sent in for approval, have led to the postponement of any formal decisions.

THE promise which a diminishing deficit in the telegraph revenue two years ago seemed to hold out has been rudely broken in the year just past. According to the Postmaster-General's annual report, the balance on the wrong side is again nearly what it was in the years preceding 1888, and double the amount at the end of 1890. This is the more disappointing seeing that the number of telegrams goes on increasing at much the same rate as heretofore. The explanation seems to be that the expenditure increases at a much higher rate, and the revenue at a rather lower rate. Increased wages paid to operators partly, no doubt, account for the former, and decreased payment for messages explains the latter. The average value of the "sixpenny" telegram continues to dwindle as customers learn to economise words, or adopt a registered address. Then, again, the Continental tariffs have been greatly reduced, and the profits from that quarter still further lessened by the cable telephone wires, traffic over which, although paid for at high prices, disproportionately reduces the number of ordinary telegrams.

FROM a commercial point of view, however, the whole report, so far as it relates to the telegraphs, is highly satisfactory. The briefer and the cheaper messages become, the greater number can be despatched by the public and disposed of with increased efficiency and speed by the department. The cheapening of telephone and private wire rentals is equally gratifying to the business community, though we do not gather that the revenue will greatly profit by it. An extension of this class of work to the telephone trunk lines will result probably in further augmentation of the telegraph deficit. Here we cannot help repeating our expression of surprise that the separation of telegraph from Post Office accounts continues to be maintained. By itself the telegraph department would never have taken up with the several unremunerative reforms into which from time to time it has been driven; and the Post Office, which does all the driving and gets most of the praise, ought to bear the burden of the loss. But as long as the accounts are kept separate so long will the afflicted telegraphs be credited—or rather discredited—with being a poorly paying adjunct of the Post Office, whereas if left to itself the telegraphs would be a highly profitable concern.

IT is somewhat sobering to note into what a small compass the life's work of even the most active amongst us can be compressed when the narrative is confined to a mere catalogue of things done, the proper appreciation of them being left to the unaided intelligence of those who may chance to be interested in the story. But "an honest tale speeds best being plainly told;" and the services rendered to the cause of electrical science by SAMUEL VARLEY are not likely to escape recognition merely because the Varley Testimonial Committee have, in the circular letter which we reprint in another column, wisely avoided all debatable dicta and limited themselves to a bald statement of fact. The rank and file of the electrical profession are not for the most part overburdened with riches; but if everyone who reads the appeal of the committee contributes out of his "lean and low ability," the recognition of Mr. VARLEY's work will be as widespread as we trust it will be substantial.

AT the meeting which was held at the Westminster Palace Hotel in July last, Mr. CROMPTON confessed to having known next to nothing of Mr. VARLEY and his discoveries until, at the end of 1888, Messrs. KING, BROWN AND CO. chivalrously elected to contest the validity of BRUSH's so-called compound-winding patent, No. 2,003 of 1878. Were the rest of the electrical profession as refreshingly candid as Mr. CROMPTON, we are afraid they would have to plead guilty to a similar state of ignorance. Indeed, the faculty which some men possess of being lost sight of is quite as astonishing as the happy knack which others have of being always in evidence.

YOUR true inventor, that is to say, one who is afflicted with a mania which keeps him for ever at the treadmill devising curiosities of ingenuity quite regardless of the existence or non-existence of any demand for them, is notoriously a sanguine man. But hope, as someone has aptly put it, is not the man for your banker, though he may do for your travelling companion. Hence the oft-told tale of failure followed by neglect, resulting but too frequently in sour suspicions of the integrity of mankind in general, and of successful contemporaries in particular.

To make invention a paying pursuit a good solid dose of business-like shrewdness is absolutely indispensable. It is necessary to seize the psychological moment for putting your patented wares upon the market; on no account must you be before your time; and there must be no illusions as to the tangibility of that asset known as fame. Pursued in this fashion, invention degenerates into mere patent-mongering, but it leads to wealth. Nevertheless, to the credit of humanity be it said, when attention has once been directed to the overlooked services of pioneering patentees, the question of whether any debt is due to them is not, as a rule, examined in any quiddling spirit, unless, indeed, like Mr. LANE FOX, they put themselves out of court by going to law.

Maidstone.—The Maidstone authorities contemplate erecting an electric lighting station, at a cost of about £12,000.

Partick.—The Police Commissioners of Partick, one of the suburban burghs of Glasgow, are about to apply to the Board of Trade for an Electric Lighting Provisional Order.

Electric Railways in London.—The Corporation of the City of London have issued a Blue Book dealing with the Electric Railway Bills introduced into the late Parliament.

Honours.—Amongst the list of honours which appeared in yesterday's papers as approved of by the Queen is the following:—Sir John Pender, K.C.M.G., M P., to be G.C.M.G.

Digitized by Google

Cardiff.—At the last meeting of the Town Council a lengthy report, which had previously been presented to the Lighting and Electric Committee by the Sub-Committee and accepted, was submitted to the Council and adopted. The report estimated the approximate cost of electrically lighting the borough at between £25,000 and £30,000.

Underground Mains in Paris.—With a view, it is said, of diminishing the chances of further explosions on their system of underground mains, the Compagnie Continentale Edison are giving their bare copper conductors a coat of tar. On the other hand, the municipal electric light engineers are trying the effect of ventilating the conduits, a fan driven by a couple of men being used at different points on the network.

Chatham.—At the last meeting of the Town Council the following motion was adopted:—"That the Corporation shall take such steps as may be necessary to acquire and purchase the interest in the Chatham Electric Lighting Company, if the said Company are disposed to sell at a price advantageous to the ratepayers—the matter to be referred to the same Committee appointed to consider the question of the Waterworks, and report."

Electric Launches on the Seine.—Last week the Paris agent of Woodhouse and Rawson United gave the representatives of the electro-technical Press a run on board the electric launch, "L'Éclair." The launch is 11 metres long and 1·8 metre beam, and draws 40cm. of water; its maximum speed is about 12 kilometres an hour, and it can run six hours at full speed. Current is obtained from a 40-cell battery of Epstein accumulators, having a capacity of 160 ampere-hours, on a discharge of from 25 to 30 amperes.

Junior Engineering Society.—This society has provided an excellent series of summer excursions for its members, extending from the 12th to the 20th of August. It has been contrived that the maximum number of places should be visited in this short space of time, including the large engineering works at Crewe, Chester, Manchester, Bolton, the Ship Canal, and Liverpool. From the programme which has been issued to members of the society the details of the excursion seem to have been arranged with a considerable amount of forethought.

Accumulator Patent Litigation in France.—Judgment in the action brought by the Compagnie Française des Accumulateurs Faure-Sellon-Volckmar (Philippart et Cie.) against MM. Rousseau and Paul Gadot has, says our Paris correspondent, just been given. M. Constant Rousseau has been held not to have infringed the patents owned by the Compagnie Française, but M. Paul Gadot has been fined 500fr. and condemned to pay 5,000fr. damages as well as the costs of the action. It is said that an appeal will be lodged against this decision, the damages awarded being deemed insufficient.

Telegraphic Rates to Australasia.—According to a Reuter's telegram the Conference of Australasian Postmasters-General, recently held at Melbourne, has decided to recommend to the various telegraphic administrations interested in telegraphy to the Far East an increase of 9d. per word in the charge from October 1st next. It is also announced that the proposal of New Zealand to join the other colonies in guaranteeing the Companies a certain proportion of any loss from the low rates has been accepted, and the tariff between New Zealand and London will consequently be reduced to 5s. 3d. per word.

Thunderstorms in Spain.—The destruction of life and property caused in Spain by storms has this year been of an unprecedented character, says a Reuter's telegram from Madrid. Not a month has passed since last May without a number of thunder and hail storms, which destroyed the crops in many districts, while the loss of life and damage through lightning has been exceptionally heavy. Telegrams received to-day (August 11th) from Saragossa bring details of the desolation wrought by storms in the districts of Borja and Ateca. At Osera a woman was killed by lightning, and at Lechando two boys met with their death in the same way, while two others were injured by the electric current.

Prescot.—The Local Board have accepted the offer of the British Insulated Wire Company, whose works are at Prescot, to light the town and district with 12 arc lamps and 70 incandescent lamps at a cost of £350 per annum for five years. The estimate of the firm included everything connected with the lighting of the town. The total cost of gas for the year ended March 31st last was £312. The Gas Company, however, had offered to make a reduction of 2d. per 1,000ft., which would amount to about £8 on the consumption of last year. Mr. Yeaman, representing the firm, explained that the whole of the new arrangements could be completed and the district supplied with the light in the course of about one month.

The Electric Lighting of the City.—The City of London Company expect to have over 500 street arcs alight by the end of October.—A meeting of the St. Bene't Fink Vestry was called last week to consider the advisability of utilising a portion of the site of the old churchyard of St. Bene't Fink for the parish benefit. The Vestry approved of an application being made by the rector and churchwardens, in conjunction with the Corporation, for a faculty to permit the City of London Electric Lighting Company to construct in the churchyard a transformation chamber or vault, and to place in it certain apparatus for the conversion of electricity. The Vestry also approved of a draft agreement by which an annual contribution will be paid by the City of London Electric Lighting Company to the parish for the general expenses of Divine service in the church.

Bristol.—On Friday Mr. Rienzi Walton, one of the inspectors under the Local Government Board, held an inquiry at Bristol relative to the application of the Town Council for permission to borrow £66,000 for the purpose of electric lighting. The Town Clerk, in reply to the inspector, said that the population of the city at the last census was 221,700. The assessment value was £1,042,974. The indebtedness of the Corporation other than as the Sanitary Authority was £268,704, and as the Sanitary Authority it was £385,918; but there was also a considerable indebtedness in connection with the Dock Estate. The Town Clerk explained that until a year or two ago they were advised by eminent authorities on electric lighting that they did wisely in holding their hands for a further development of the science. They now proposed to have an installation, and the money was required for the erection of a central station and for laying down the necessary plant. There was no objection to the application.

Hastings.—Some three years ago (Sept., 1889) the Hastings Town Council were led to believe that they would be doing a good thing for themselves by undertaking the electric lighting of the sea front, as they would have "with the dust destructor boiler" sufficient power for the purpose, and would save £180 per annum upon the £450 then being paid. We now learn from the local papers that the Corporation are not disposed to take upon themselves the work of lighting the public streets, and that at the last meeting of the Council a report was presented recommending that arrangements be made with the Electric Light Company for lighting the whole three miles of the sea front, though for the present the proposal remains in abeyance. At present only three-quarters of a mile of the most frequented portion of the esplanade is electrically lighted, 16 lamps, at intervals of 100 yards, being erected. If the new proposal is carried into effect there will be 51 arc lamps, 80 yards apart, and the cost at £25 per lamp will be £1,275. After midnight each alternate light is to be extinguished.

Southport.—The scheme and plans for the electric lighting of Southport, prepared by Mr. Geo. Wilkinson, involving the expenditure of £28,000, exclusive of land, were unanimously adopted by a special Town Council meeting, held on Monday night last. The system adopted is that of high-pressure alternating currents, and the generating station is to be erected on a site adjoining the present gas works, 1½ miles out of town. Special provision is being made in the generating station for burning refuse fuel from the gasworks, and water is available for condensing. With these economies and the advantage to be derived from working the gas and electric lighting businesses together, the actual cost of producing the electrical energy is expected to be very low. Trunk mains (in duplicate) will be laid to transformer substations in the town

Digitized by Google

and residential districts of Hesketh Park, where low-pressure distributing mains will be laid. The full equipment of the station will be as follows:—Three sets (horizontal engines and dynamos), each equal to an output of 100 units, two 50-unit sets, and one 25-unit set, the alternators working in paralled. It is proposed to supply electric current to consumers by meter, at 6d. per unit, until the profits of the business justify a reduction.

Launceston (Tasmania).—The Launceston Town Council lately adopted a report in favour of electrically lighting the city, the scheme adopted being one prepared by Mr. K. L. Murray, of Melbourne. Mr. Murray's plan, the execution of which will cost some £45,000, involves the use of the water of the South Esk River to supply the necessary power. It is proposed to run a 42in. pipe from a generating station to be situated at the first basin, which is about 1¼ miles from the south-west boundary of the city, to a point 55 chains up the river, where will be the race and intake. The total head from this point to the first basin is 110ft.; but, the station being 35ft. above the ordinary level of the basin, allowing an effective suction of 15ft., 90ft. will be the available head. Making liberal allowance for all losses, 470 H.P. is by this means obtainable at the turbine shafts, whilst any possible future increased demand for light will be met by a further installation of a 40in. pipe laid upon the top of the first, giving an additional 390 H.P. The dynamos will be coupled direct to the turbines, five of 20 H.P. each being used for arc lighting, and six of 90 H.P. each for incandescent lighting. The current will be conveyed into the town by overhead mains, suspended from steel bearer wires. It is proposed to light the business part of the town with 125 arc lamps, fixed in the middle of the streets on wooden poles 30ft. high. The incandescent lighting dynamos will supply current at 2,000 volts, to be transformed down to 100. One machine is to be used for lighting the streets in the residential districts with 200 50-c.p. lamps.

The Postal Telegraph Service during 1891-92.—The following extracts from the thirty-eighth annual report of the Postmaster-General relate to the telegraph service:—The telegraph money order business, although restricted until the last month of the financial year to head and branch post-offices only, showed a considerable expansion, there having been 42,055 such orders issued in 1891-92, as against 30,196 in 1890-91, while the amount remitted was £157,428, as compared with £112,570. The following table shows the number of telegrams and the receipts thereon for the year ended March 31st last, and also for the preceding year:—

Class of Telegrams	Year.	Number.	Increase.	Receipts.	Increase.
Ordinary Inland ...	1891-92	57,085,939	2,969,526	£1,848,974	£74,352
„ „	1890-91	54,116,413	—	1,774,622	—
Press (Inland).....	1891-92	5,180,278	176,869	116,247	3,098

Totals	1891-92	69,685,480	3,276,269	2,226,472	77,920
„	1890-91	66,409,211	4,005,812	2,148,552	106,799

* Decrease. † Of this sum £4,616 was received in fees for conversations on the Paris telephone.

It will be seen that the increase in the number of messages of all kinds over that of the previous year is 3,276,269, or 4·9 per cent. The average value of an inland telegram is now 7·77d., as compared with 7·87d. for last year. The results of the working of the London-Paris telephone have been satisfactory. The number of conversations has increased from 1,221 during the month of April, 1891, to 2,157 in April, 1892.

Telegraphic Communication with Lighthouses.—The following is the latest programme of the Royal Commission appointed to inquire into electrical communication between lightships and lighthouses and the shore in England, Ireland, and Scotland:—Monday, August 15th, the Commission assembled at the North-Western Hotel, Liverpool, where they met the Mersey Docks and Harbour Board, with whom they visited the Mersey light vessels. Tuesday, August 16th: Visit to Liverpool lighthouses thence to Holyhead, thence to Kingstown. Wednesday, the 17th: Conference with the Irish Lights Commissioners, and visit to the Kish Lightvessel and the Howth Bailey Lighthouse. Thursday, the 18th: Commission left Kingstown to visit light stations on the east coast of Ireland, thence to Milford Haven. To-day (Friday), the 19th: The Commission goes on board H.M. despatch vessel Enchantress, at Milford, and visits Caldy, Helwick, Scarweather, Nash, Flatholm, and Cardiff. Saturday, the 20th: Visit to the Scilly Isles. Monday, the 22nd: Visit to Bishop Rock, Round Island, and Seven Stones light vessels, Longships, the Lizard, and Eddystone. Tuesday, the 23rd: Examination of Swanage Bay, Anoil Point, the Needles, and Portsmouth. Wednesday, the 24th: Visit to Dover, Goodwin Group, and Ramsgate. Thursday, the 25th: Visit Thames entrance and group of lighthouses and lightships, as far as Stairborough. On Wednesday, the 31st, the Commission goes to Edinburgh, and on the following day will confer with the Northern Lighthouses Commissioners, visiting May Island and North Carr the following day.

The Birmingham Accumulator Cars.—The working of the accumulator cars on the Bristol Road line of the Birmingham Central Tramways Company's system during 1891-92 has resulted, according to the Directors' report, in a loss of £1,679. The total receipts were £10,422; 188,760 miles have been run, and 1,382,997 passengers have been carried by the electric cars. The report, which will be found in another column, states that the loss is chiefly due to the heavy charges for renewal of batteries, and that the Directors have under consideration a contract for the maintenance of the batteries, which, it is hoped, will tend to material economy. The following detailed figures will be of interest:—

Average per mile run. d	d.		£ s. d.	£ s. d.

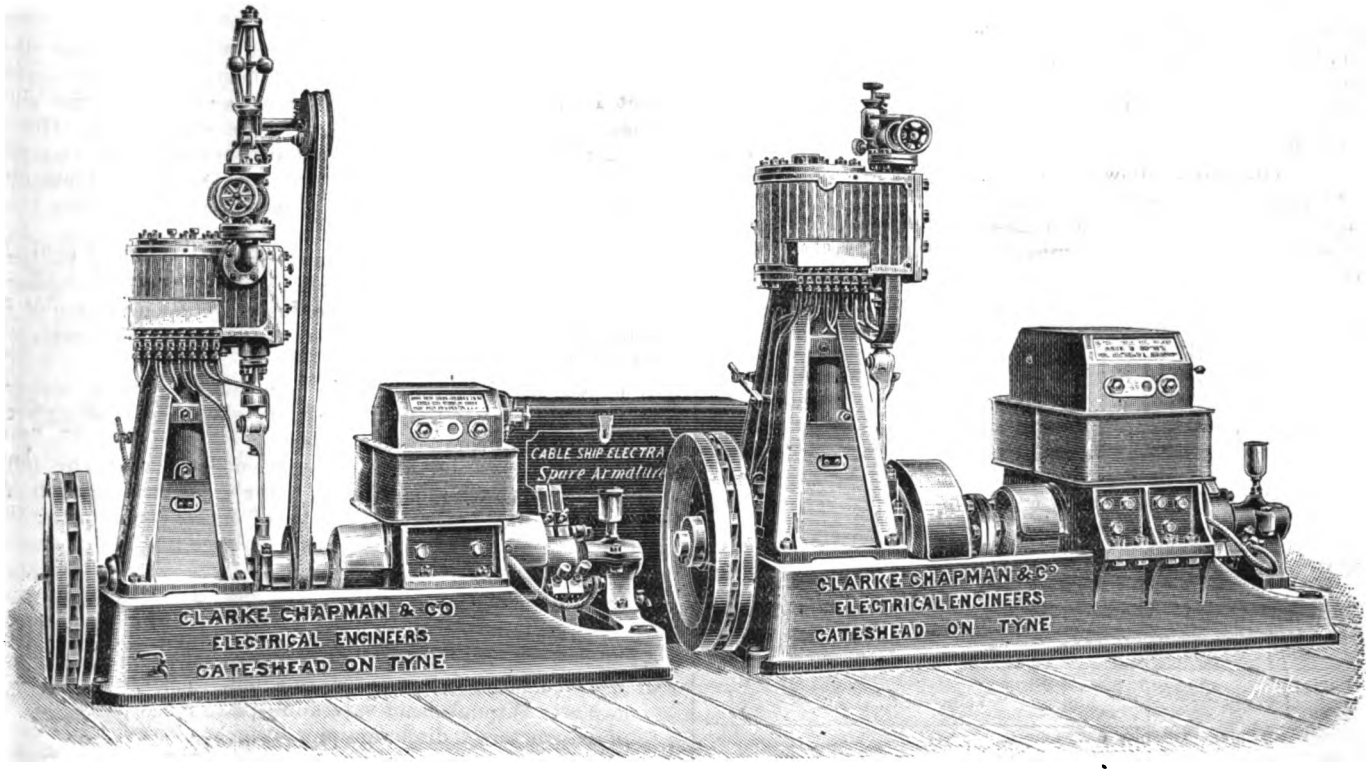
THE ELECTRIC LIGHTING PLANT OF THE CABLE SHIP "ELECTRA."

The cable ship "Electra," belonging to the Eastern Telegraph Company, has recently been fitted with a new electric lighting plant. The old machinery consisted of four old-fashioned Gramme dynamos, each giving 35 amperes at 100 volts at 1,200 revolutions, and driven through belting by two Willans three-crank engines of a very early form, running at 400 revolutions. Two sets, shown in the accompanying illustration, have now been provided, one giving 185 amperes, and the other 75 amperes, both at 65 volts. The dynamos and direct-coupled engines have been built by Messrs. Clarke, Chapman, and Co., of Gateshead. The engines are of a very substantial and compact design, and are of the inverted vertical single-cylinder open type. The standards consist of a double A frame, in one casting. The crossheads have large cylindrical bearing surfaces. The 185-ampere set runs at 250 revolutions, the floor space occupied being 7ft. by 3ft., and the engine is provided with a flywheel governor acting on the eccentric. The smaller set runs at 310 revolutions, the floor space occupied being 5ft. 10in. by 2ft. 6in., and the engine being shorter there is head room for a Pickering governor acting direct on the valve spindle. The steam pressure employed is 80lb. when supplied by the main boilers, and 60lb. when supplied by the donkey boilers. The armatures are both drum-wound, and the fields are compound-wound. A switch-board with nine circuits distributes the current. It includes an arrangement whereby the well-known method of detecting a leak in a lead by putting the opposite lead to earth through a voltmeter can be easily carried out. A projector with an 18in. mirror is mounted on the flying bridge, and is provided with diverging lenses. It is hoped that the beam will enable buoys to be sighted at a distance of two miles. Groups of glow lamps, consisting of six 16 candle lamps, are preferred to arc lamps for night work on deck. A group of five lamps is fitted immediately under the bow for giving light for work over the bow.



The Electric Lighting Plant of the Cable Ship "Electra."

CONDENSERS AND PUMPS.*

Condensers are of two types, viz., Jet Condensers, in which the steam and condensing water mix in a common vessel, from which both are pumped by the air-pump; and Surface Condensers, in which the steam generally passes into a chamber containing a number of brass tubes, through which the condensing water is made to circulate. The latter form is generally adopted where water is bad, as it enables the same feed-water to be passed through the boiler over and over again, and, under favourable circumstances, a vacuum of 28in. can be obtained, while 25in. to 26in. is as much as can be expected with jet condensers.

The capacity of a jet condenser should not be less than one-fourth of the low-pressure cylinder, but need not exceed one-half unless the engines are very quick running; one-third is a good average ratio. Large condensers require more time for forming the vacuum, while small condensers are liable to flood and overflow back to the cylinders. The amount of condensing water required per lb. of steam condensed varies with the temperatures of the exhaust, of the "hot-well," and of the condensing water. (The "hot-well" is the receptacle into which the air-pump delivers the water from the condenser.) The feed-water is obtained from the "hot-well," which should be maintained at 110° to 120° F. Sometimes even 130° F. can be got with care.

Surface condensers occupy more space than jet condensers, and require a second pump for circulating the condensing water generally, though the air pump may be smaller than that required for an equivalent jet condenser. The amount of cooling or tube surface depends upon the difference between the temperature of the exhaust steam and the average temperature of the cooling water, and on the thermal conductivity and thickness of the metal tubes. For copper and brass tubes in good condition the rate of transmission is about 1,000 units (equivalent to about 1lb. of steam condensed) per square foot

* All rights reserved. From a forthcoming work by Messrs. Geipel and Kilgour (*The Electrician* Printing and Publishing Company).

Digitized by Google

per 1°F. difference of temperature per hour. With the hot-well at 110° and the cooling water at 60°, the average difference is 25°, and 25lbs. of steam should be condensed per hour per square foot. In practice allowance must be made for the working conditions of the tubes, and half the above, *i.e.*, $\frac{1}{2}$lb. of steam per 1°F. difference is nearer the usual allowance; and under the above conditions about 12·5lbs. of steam would be condensed per square foot per hour, which is considered very fair work. In marine engines an allowance of 1·5 to 3 sq. ft. per I.H.P. is made according as the terminal pressure of exhaust varies from 6lbs. to 30lbs. (absolute); for the tropics 20 per cent. more, and for cold climates 10 per cent. less suffices.

The tubes are generally of brass, No. 18 S.W.G. thick, and from $\frac{1}{2}$ to 1in. diameter, according to the length of the tubes; they are mostly $\frac{3}{4}$in. in diameter, and spaced at a pitch of $1\frac{1}{4}$in., while the tube-plates, which are also of brass, are $1\frac{1}{8}$ to $1\frac{1}{4}$in. thick for $\frac{3}{4}$in. tubes. The length of the tubes, when unsupported between plates, should not exceed 120 diameters.

If H = total heat of 1lb. of exhaust steam in British Thermal Units (B.T.U.),
t = temperature F.° of hot-well,
t_1 = temperature F.° of cooling water on entering,
t_2 = temperature F°. of cooling water on leaving,
Q_1 = quantity in lbs. of cooling water per lb. of steam for jet condenser,
Q_2 = ditto for surface condenser;

$$Q = \frac{H - t}{t - t_1},$$

$$t = \frac{H + Q_1 t_1}{1 + Q_1} \text{ for jet condenser,}$$

$$Q_2 = \frac{H - t}{t_2 - t_1},$$

$$t = H - Q_2 (t_2 - t_1) \text{ for surface condensers.}$$

N.B.—H - t = 1,050 approximately.

Values of Q_1 and Q_2 for different temperatures of cooling water when H = 1,150 t = 110, and t_2 = 100 in case of Q_2:—

	Values of t_1.				
	40	50	60	70	80
Q_1	15	17	21	26	35
Q_2	17	21	26	35	52

Area of injection orifice should be such as to allow a velocity of flow of water not exceeding 1,500ft. per minute. It is better to have a large orifice and to control the flow of water by an injection valve.

Area of orifice in square inches = lb. water per minute ÷ 650 to 750.

= area of piston ÷ 250.

The cooling or circulating water in surface condensers should travel some 20ft. lineally through the tubes. In small condensers, where this is not convenient and the water only circulates twice through short tubes, the rate of flow must be reduced.

A replenishing cock should be fitted to allow of the passage of part of the circulating water into the air-pump suction to provide for water lost in drains, blowing off, leakage, &c. This may have $\frac{1}{10}$ the area of the feed pipe. A cock should be fitted close to the exhaust inlet for introducing caustic soda when required to dissolve grease off the tubes.

Air Pumps.

Air-pumps are used to draw the condensed water from the condenser to the hot-well, together with the air originally contained in the water, or which may find its way in through glands, &c., and with jet condensers they also draw the cooling water. A cubic foot of ordinary water contains about 0·05 cubic foot of air at atmospheric pressure, which expands in the condenser to about 0·4 cubic foot of air, hence the term air-pump.

The efficiency of a single acting air-pump may be taken at 0·6 to 0·4 and generally 0·5, while that of the double acting pump may be 0·5 to 0·3, say 0·4 on average. For jet condensing the volume of the air-pump should be theoretically 1·4 times the volume of condensed + cooling water; for good working it should be from twice to thrice that required by theory. Or if

v = volume of condensed water per minute in cubic feet.
V = volume of cooling water per minute in cubic feet.
n = number of strokes (useful) of air-pump per minute.
A = volume of air-pump;

$$A = 2{\cdot}8\frac{v + V}{n} \text{ for single acting pumps.}$$

$$= 3{\cdot}5\frac{v + V}{n} \text{ for double acting pumps.}$$

Since, for surface condensing, the air-pump does not draw the cooling water, and as the feed-water being used over again should not contain so much air, it would appear that the air-pump might be much smaller than for jet condensing. However, surface condensers are frequently arranged for use as jet condensers in case of mishap, and with surface condensing a better vacuum is expected, so that for surface condensing the air-pump is only slightly less than for jet condensing. In actual practice the air-pump is made from $\frac{1}{10}$th to $\frac{1}{25}$th the capacity of the low-pressure cylinder, according to the number of expansions and nature of condensers while a comparison of a number of marine engines by different makers shows a ratio of $\frac{1}{16}$th to $\frac{1}{21}$st.

If expansion joints are used in the exhaust pipe a copper bellows joint is better than the ordinary gland and stuffing-box type, through which air is apt to leak.

Air-pump valves should have sufficient area that the full quantity of cooling and condensed water in jet condensation in passing does not exceed a velocity of 400ft. per minute; in practice the area is larger than this. A large number of small valves is perhaps better than one or two large valves which are sluggish owing to their inertia. The clearance space between head and foot valves should not exceed $\frac{1}{15}$th the capacity of the pump as ordinarily constructed.

If a = area through foot valves in square inches,
a_1 = area through head valves in square inches,
d = diameter of discharge pipe in inches,
D = diameter of the air-pump in inches,
S = speed (useful) in feet per minute;

$$a = \frac{1}{1{,}000} D^2 S,$$

$$a_1 = \frac{1}{800} D^2 S,$$

$$d = \tfrac{1}{3}\tfrac{1}{3} D \sqrt{S}.$$

If there be no air vessel or receiver, d should be 10 per cent. larger. An air pipe should be fitted to the hot-well $\frac{1}{4}$th the diameter of the discharge pipe.

Circulating Pumps.

The size of these depend chiefly on conditions mentioned for air-pumps, and they may bear a constant relation to the air-pump as to size, or to the L.P. cylinders.

Air-pump.	Circulating pump.	Ratio.
Single acting	Single acting	0·6
Single acting	Double acting	0·31
Double acting	Double acting	0·52

or if V = volume of cooling water in cable feet per minute
S = length of stroke in feet,
n = number of strokes (useful) per minute,
C = capacity of pump in cubic feet,
D = diameter of pump in inches;

$$C = \frac{V}{n},$$

$$D = 13{\cdot}55\sqrt{\frac{V}{nS}}.$$

Digitized by Google

Circulating pump valves should be of sufficient area that the mean velocity of flow does not exceed 450ft. per minute. High velocities tend to wear out the valves, and cause undue resistance in the pump. In the suction and delivery pipes the velocity should not exceed 500ft. per minute, or for large and easy leads 600ft. per minute. Better results, however, will be obtained by using larger pipes so as to reduce the velocity, especially if the pipes are long. For single-acting pumps the suction may be smaller than the delivery, if the pump be below the water-level.

If a = minimum area through valves in square inches,
d = minimum diameter of pipe in inches,
A = area of pump in square inches,
D = diameter of pump in inches,
S = mean speed (useful) of pump in feet per minute;

$$a = \frac{A\,S}{450},$$

$$d = \frac{D\sqrt{S}}{K},$$

where K varies from 22 for small pumps to 25 for large pumps, while for the suction of single-acting pumps it may be 27.

Air vessels should always be fitted, which for single-acting pumps may be twice the capacity of the pump. An air-pipe should be fitted to the highest points of the water passages for escape of air to enable the condenser and pipes to run full. If the speed of the circulating pump cannot be varied independently, it is advisable to fit a water-valve between the two ends of the pump, so that the discharge may be varied to suit the requirements.

Centrifugal pumps may be used advantageously where the water is at the level of the pump. Some advantages are that if worked by an independent engine (as usual) the supply of cooling water can easily be varied, and the power required is reduced in proportion; the cooling water can be started before the main engines, so keeping the condenser cool; there is an absence of valves and shock to the condenser which there is not with reciprocating pumps. On the other hand, centrifugal pumps are more expensive and require rather more attention. Some of these advantages are obtainable by use of an independent reciprocating pump.

The inlet and discharge pipes should allow for a velocity not exceeding 400ft. per minute, while the diameter of the fan is two to three times that of the pipes. The peripheral speed of the fan must exceed 400ft. per minute, and is generally 450 to 500ft. per minute.

If V = cooling water in cubic feet per minute,
d = diameter of pipe in inches,
D = diameter of fan in inches,
B = breadth of blade in inches,
r = revolutions per minute of fan;

$$d = \sqrt{\frac{V}{2{\cdot}18}},$$

$$D = \frac{1{,}700}{r} \text{ or more},$$

$$B = \frac{V}{4{\cdot}7\,D}.$$

The fan should be of gun-metal, and the blades as thin as possible. The shaft should also be of gun-metal or cased with gun-metal.

Strainers should be fitted to the inlet of the suction pipe, and the aggregate area of the passages should be from two to four times the area of the pipe, according to the velocity of flow in the pipe. Owing to the difficulty experienced in cleaning strainers when under water, they are sometimes fixed in a cast-iron vessel near the suction entrances to the pump, with a door arranged in some convenient position for cleaning.

When the water level is below that of the pump a foot valve should be fitted just above the surface of the water. A door should be provided for examining the valve without disturbing the suction pipe.

Feed Pumps.

These should be of at least double the capacity found by calculation from the amount of water required for the engines, to allow for blowing off, leakage, slip in the pumps themselves, &c., and to enable the pump to keep down steam in case of sudden stoppage of the engines when the fires happen to be brisk. In addition, for all important plants there should be either a duplicate feed-pump or an injector to act as stand-by in case of accident. The speed of the plunger or piston may be 50ft. per minute, and should never exceed 100ft. per minute, else undue wear and tear of the valves result, and the efficiency is reduced. If the pump be required to stand idle without continually working, the plunger or piston and rod should be of brass.

In pumping hot water, the water must be above the level of the pump barrel.

If D = diameter of barrel in inches,
S = stroke in inches,
n = number of useful strokes per minute,
w = cubic feet of water pumped per hour,
W = lbs. of water pumped per hour;

$$w = 1{\cdot}7\,D^2Sn.$$

$$W = \frac{D^2\,Sn}{36{\cdot}6}.$$

If $Sn = 50$,

$$W = 1{\cdot}36\,D^2,$$

and

$$D = \sqrt{\frac{W}{1{\cdot}36}}.$$

The duty of pumps is expressed by the number of foot pounds of water raised per 100lb. of coal consumed in the boiler. "Low-duty" pumps give about 50 to 70 million, and "high-duty" 95 to 110 million or slightly above. With ordinary direct-acting pumps, where steam is maintained at initial pressure throughout, considerably less than a duty of 50 million pounds may be expected, especially with small pumps. A test made by one of the authors on such a feed pump gave but 21 millions foot pounds duty. It was also found at this test, which was made in feeding a 20 actual H.P. water-tube boiler driving an engine indicating 35 H.P., that 17 per cent. more coal was required when feeding with the feed-pump than when using an influx injector, although the feed-water was heated by the exhaust steam to 212°F. when using the pump.

By the use of a flywheel better results may be obtained, as the steam may be used expansively. Messrs. Worthington, in their high-duty pumps, use compensating water cylinders which oscillate so as to absorb power during the first part of the stroke, delivering the power during the second half; by this means they are able to work the steam expansively without the use of the complications introduced by the flywheel, and by adopting this system combined with compound cylinders they claim the highest duty.

The Brush Company make a three-throw feed-pump, which is geared to a high-speed engine with early cut-off, from which considerably more economical results may be expected. Arrangements are made for throwing out either one or two plungers to reduce the flow.

The feed-pump may be arranged to stop and start automatically by operating the steam valve on the pump by a float in the boiler. Feed non-return valves should have a diameter sufficient to allow of a lift not exceeding $\frac{1}{8}$in., to obviate the hammering action of the valve. Rubber valves may be used for cold water, but brass, rubber composition, or other suitable material is required for hot water or oil. If a new pump will not start, it may be due to imperfect connections or temporary stiffness of pump.

Unless the suction lift and and length of supply pipe be moderate, a foot-valve, a charging connection, and a vacuum chamber are desirable. The suction-pipe must be entirely free from air leakage. If the pump refuses to start lifting water with full pressure on, on account of the air in the pump chamber not being dislodged but only compressed each stroke, arrange for running without pressure until the air is expelled and water flows. This is done with a check-valve in the delivery-pipe, and a waste delivery which may be closed when water flows.

The annexed diagram shows an arrangement of connections suggested by Messrs. Worthington. B is the suction-branch,

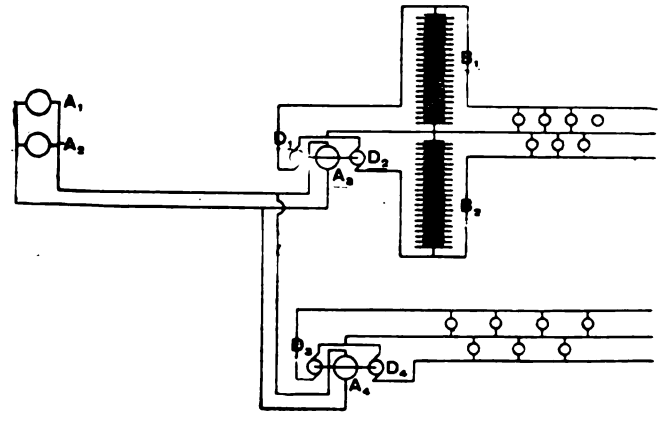
pipe for filling the pump chamber and suction-pipe from the delivery-pipe before starting.

POWER TRANSMISSION BY ALTERNATING CURRENT.*

BY GISBERT KAPP.

Some two years ago the municipal authorities of Cassel, in Germany, determined to become purveyors of electric light, and to place the generating station on the site of the waterworks pumping station, which is situated on the River Fulda, about four miles from the town. It would, of course, have been possible to lay down an ordinary alternating-current station, but this would not have been a good solution. In the first place, the total number of lamps that could have been installed would not have exceeded 2,500 of 16-c.p., corresponding with the maximum of 200 H.P. available at the pumping station; and in the second place, the low load factor of an alternating-current supply would have operated against the very object the municipality had in view, namely, to make the best use possible of their existing power plant. In order to carry out this object, it was obviously necessary to adopt some system of storage so that the turbines could work at full power continuously. With such a system the number of lamps installed could, at the same time, be materially increased. Thus, an ordinary direct-current station with batteries might have given these advantages, but for one, and that a very serious obstacle, namely, the great distance between the generating station and the town. It was evidently necessary to work at high-pressure and to use some system of transformation at a sub-station in the town; but high-pressure direct-current dynamos present difficulties which one would rather avoid than face, whilst the insulation of some 1,000 storage cells in series when charging, and their grouping in ten parallels of 100 and regulation whilst discharging present very serious difficulties and introduce complications. It wil thus be seen that neither the ordinary alternating-current system, nor the ordinary direct-current system with batteries, nor the so-called Chelsea system, presented a satisfactory solution of the problem involved in the lighting of Cassel. It was nevertheless solved in a very successful manner by a German engineer, Herr Oskar von Miller, who had been called in by the municipality to carry out the work. The plan adopted by von Miller was briefly this. He determined to transmit power by single-phase alternating current from the generating station to a sub-station or rather to two sub-stations in Cassel, and to use this power for the supply of direct-current on the three-wire system. At one of the sub-stations he established a battery which is charged during the hours of light load, and assists the dynamos during the hours of heavy load, so that the maximum power available shall suffice for 3,500 60-c.p. lamps wired.

The general arrangement of this installation is shown in the accompanying diagram:—A_1 A_2 are two 60-kilowatt alternators at the generating station. The current is transmitted through an underground concentric cable to the sub-stations. The alternators are designed for a terminal pressure of from 2,000 to 2,200 volts; and the loss in transmission, when both are working full power, is under 10 per cent. Each sub-station contains an alternating continuous-current transformer, consisting of a 60-kilowatt alternator,



A_3 A_4, coupled with two continuous-current dynamos, one on either side, D_1, D_2, and D_3, D_4 respectively. The latter machines are connected with each other and with the mains in the usual way adopted in three-wire distribution. At one of the sub-stations there is a battery, B_1 B_2, also arranged on the three-wire system. The mains throughout the district are coupled so that the battery sub-station can supply current to the other sub-station through the town mains. To start any one of the two transformers it is only necessary to switch on the two dynamos which begin to work as motors, and after observing by a synchroniser that the speed of the alternator has reached the required amount to close the high-pressure alternating-current switch when the alternator works as a motor supplying power to the two dynamos which are directly coupled to it.

It will thus be seen that not only are the two alternators at the generating station worked in parallel, but also the two sub-station alternators erected in different parts of the town are worked in parallel. The dynamos are Brown's design, and the alternators are of the type known under my name, both made by the Oerlikon Engineering Works, but I must distinctly state that I can claim no credit whatever for the Cassel installation; and that the whole credit for this (probably the earliest) example of power transmission by alternating currents is due to von Miller, who, at a time when most electricians were still in doubt as to the possibility of parallel running, boldly laid down a plant, the success of which was not only dependent on parallel running, but also on the economical and safe transmission of power by single-phase alternating current, using for this purpose the ordinary type of alternator as made for lightning. The plant was started on May 15th last year, and has been working since then without a hitch.

APPLICATION OF DESTRUCTORS, PARTICULARLY TO THE ELECTRIC LIGHTING OF EDINBURGH.*

BY PROF. GEORGE FORBES, F.R.S.

The object of this Paper, said the author, was to enable the citizens of Edinburgh to see the enormous natural advantages which exist in their city with relation to electric lighting. The advantages were such as would enable the people of Edinburgh to obtain the electric light at a price lower than gas, which could hardly be considered possible in any other town. First, as to the use of destructors, that was, the use of furnaces for burning the city ashbin refuse, which were recognised as the best way of getting rid of refuse, and the means of using these destructors for fuel to generate steam. Referring to any load diagram of an ordinary central station, they would find that during the greater part of the day the machinery and boilers were lying idle; for two hours only were they working at their maximum. To have these dynamos and engines standing without earning any money was very serious, but there was another serious result, and that was that the boilers required to be fixed up for simply a two hours' run. Every engineer knew what a low efficiency there would be from coal used in that manner. The only cure for this difficulty was some system of storage. The President of the Section had referred to the storage by means of hydraulic accumulators, which Lord Armstrong has so largely introduced; he has also alluded to storage—hydraulic storage in reservoirs—both at Geneva and Zurich. It was exactly following out those ideas that the author would suggest how the difficulty of storage should be overcome in Edinburgh. The reason why Edinburgh was peculiarly well situated was, that there was very high land in the immediate neighbourhood of the town—he referred specially to Arthur's Seat.

The author's first notion was to use Dunsapie Loch as a reservoir, the idea being that a steam-engine should be used at the low level, continually pumping water up to the high level, and at the lowest part of this, pipes and turbines should be attached for driving dynamos; this arrangement was exactly the same as that employed at Zurich. A further examination and consideration of the locality showed that by a slight additional expense they gained enormous advantages. Looking from the summit of Arthur's Seat, in the direction of Portobello, there was a gully which, by means of a very short dam, would enable them to make a reservoir which would not be in the least unsightly to the neighbourhood of Edinburgh, and, in fact, would be invisible save from the Portobello side of the hill. If such a dam were built, the pipe line would then be taken down to Lochend, nearly a mile distant. The height of the reservoir would be 725ft., and the height of Lochend 83ft.; they might also use Dunsapie Loch and St. Margaret Loch—in fact, there were several ways of doing the work. If Dunsapie were deepened to 10ft., it would contain a million and a-quarter cubic feet of water; but by building a dam near the summit of Arthur's Seat they got a quantity of water equal to 28,000 H.P. working for an hour, that is on the assumption of 75 per cent. efficiency on the turbines and pipes. The cost of the pipes carried from the summit of Arthur's Loch came out at the rate of £1 per horse-power. They would be able to see what could be done with this horse-power. The Berlin load curves showed that the maximum demand on a mid-winter day was four times the mean; secondly, if engines were constantly supplying power, storing what was not wanted, the storage capacity must be equal to maximum output working for about two hours; thirdly, the maximum output at any moment in the year was about six times the mean output of the whole year. Working from these facts, the author found that there can be obtained from the 28,800 H.P. hours available in the reservoir, a maximum output in the central station of 12,500 H.P., and that 3,000, continually working in the form of steam-engines, would make a total of 15,500 H.P. There is by this means saved the cost of 12,000 H.P. boilers and engines which would probably cost £200,000, replacing it by pipes and turbines, pumps and reservoir, probably costing not more than £35,000 altogether. Pumping engines and turbines were now so perfect that it would be possible to get a horse-power delivered from 3lb. of Welsh coal. Experience showed that, including the coal wasted in getting up steam and banking fires, even when using the best appliances of the modern central station, 5lb. of coal at least was required for every horse-power. There was then a saving of about 2lb. of coal per horse-power by keeping the engines working at their maximum. The maximum demand in winter was six times the mean of the year; thus, with a maximum of 15,625 H.P., there was a mean output of 2,600 H.P. all the year round. A saving of 2d. per lb. of coal per horse-power amounted to 20,000 tons, which at £1 per ton meant a saving of about £20,000 per year. These facts illustrated very clearly the enormous advantage of storage, which could be so easily gained by utilising the natural advantages of the City of Edinburgh.

The author then dwelt on the advantages of the use of destructors. There was no doubt that the use of destructors for getting rid of refuse, and for getting up steam for electric lighting purposes, would play an important part in the future, but in most towns it would be impossible to get the full advantage from the destructors, because they must be burning refuse day and night, whereas for electric lighting purposes, or the distribution of power, it was only during certain times of the day that there was a demand, so that the heat from the destructors was wasted for the greater part of the day; but by the hydraulic storage in Edinburgh they would be able to use destructors with the greatest advantage. After a reference to the destructor at Leeds, the author said that steam had not been largely used at Leeds, but at Southampton and one or two other places it had been largely used. At Southampton the boilers (locomotive) were simply placed in the main flues, without any attempt to drive the products of combustion through the flues, with the consequence that there was a very bad economy, and it required 75lb. of ashbin refuse to give a horse-power for one hour. The author had made numerous experiments on the heating properties of ashbin refuse, and there was not the slightest doubt that in the great majority of towns the ordinary ashbin refuse as a heat-producing power would mean that 10lb. would equal 1lb. of ordinary coal.

ON A NEW FORM OF GAS ENGINE.*

BY JOSEPH DAY, A.M.INST.C.E.

In this engine simplicity has been the principal object sought. The construction of the engine is as follows:—The piston is of the trunk form, and through a connecting rod works on to the crank pin. The crank works in an enclosed chamber, the crank shaft projecting through a boss bearing, terminating in a gland. On the upward stroke of the engine a partial vacuum is produced by the retreat of the piston, and this induces a flow of gas and air, in controlled proportions, into the crank chamber through an automatic valve. On the downward movement of the piston the mixture thus introduced is compressed—in practice, it is compressed to about 2lb. to the inch—and by this means is possessed of sufficient motive power to charge the working end of the cylinder. This is accomplished by the following device:—Communicating from the crank chamber to the lower part of the working end of the cylinder is a port or passage, and this is closed by the piston until the latter, at the end of its stroke, uncovers it. Immediately the gas mixture, being compressed as explained, flies up through the passage and charges the cylinder, the piston returns, closes the port, compresses the mixture in the usual way against an ignition tube, and an explosion results, causing the descent of the piston. The exhaust of the waste products is accomplished by the opening of a somewhat similar port communicating to the atmosphere *opposite* the inlet port above described, which is opened by the piston slightly in advance of the opening of the inlet port. Thus, when the incoming charge is admitted, the explosion in the cylinder has been reduced to atmospheric pressure. The incoming charge is made to assist in the clearance of the waste products by its being diverted upwards by a fin on the top of the piston, and thus setting up an eddying action, tending to drive out the contents of the cylinder through the open exhaust port. Thus it will be seen that with one piston and one cylinder an impulse is obtained at every revolution of the engine. It will also be apparent that the engine will run with equal facility and efficiency in either direction. The speed obtainable is very great, there being no tappets, cams, or levers, and in a small engine as much as 1,100 revolutions per minute have been obtained. At this speed firing was irregular, but at 500 revolutions the explosions were absolutely regular. For the same reason the engine runs extremely quietly. The writer claims to have produced an engine—(1) With fewer working parts than any other; (2) that occupies less space; (3) that without any alteration will run in either direction; (4) that, owing to the absence of friction, possesses a high degree of mechanical efficiency; (5) that runs more silently than any other gas engine.

SUMMER SCIENCE.

That any institution, however good its organisation, will eventually become obsolete is a matter so obvious as hardly to require comment. Its anachronisms may indeed be caused by the accurate appreciation by its founders of the immediate needs of their time, and by the adequacy of its functions in the past to supply a demand which either no longer exists or which exists in modified degree and in altered form. In the British Association, which was founded by Sir DAVID BREWSTER in 1881, the hopes of its originators have been signally fulfilled, in so far as the aim was the dissemination of miscellaneous science.

In the early days of the century which will so soon itself be a thing of the past, men had not learnt to look on science as the great force of the age; that which truly changes or tends to change the condition of rest or motion of human thought and affairs. It was a state of things as then unheard of to sit metaphorically and actually at the feet of a lecturer, expounding to his audience, in so far as their capability of comprehension allows, not only the known facts and discoveries of science, but exhibiting, with the shells of the hypothesis from which they sprung still adhering to them, the half-fledged notions of some leading thinker. As a promoter of scientific popularity much credit may be taken and much good has been done by the British Association. Its members are more than recruited yearly by those who take an intelligent interest in, although they may have no direct connection with, scientific bodies. It has gone far to prove the interest of the general public in investigations geographical, geological and otherwise; and no doubt has given a stimulus to

Digitized by Google

the work of persons whose position lies between that of the amateur or dilettante scientist, and that of the "savant." It also gives an occasion for the great men whose departments rarely coalesce, and whose work approximates in no practical degree, to interchange ideas and have an opportunity of acquainting themselves by personal contact with their fellow workers. It enables the physicist to have the pleasure of hearing from the lips of a distinguished foreign biologist such sentences as this, "There are two reasons for this hypothesis; the first is that it is a good one, the second that we *must* have a hypothesis." Moreover, if we may judge from the last and one or two of its more recent gatherings, the British Association seems likely also to become a *rendezvous* for savants of other countries who in this way combine their own pleasure in the attractions of travel and of science, with the honour they confer on the town chosen for the meeting of the society.

But not wishing for a moment to undervalue these considerations, it seems a pity that the practical result of such an Association should be so unsatisfactory. Whether or no the advancement of knowledge in any great degree other than in the sense of rendering it popular, is furthered by those summer picnics, has long since ceased to exercise the scientific mind. There is a tacit understanding that the majority of the Papers will not contain the best and most serious work of their authors; in many cases the discussions are merely nominal, and we look in vain for evidence of that desire for members whose work shall not only be well up to the mark, but of real original value, which characterises another itinerant society, the Physiological. This society strives to exclude from membership all persons, however good in their general medical work, who are not of sufficient scientific eminence to merit the title of Physiologists. At present it occasionally happens at British Association meetings that a man exceedingly good in his own line, and who has been at some pains to be present at a Paper the subject of which is of interest to him, although outside his own work, is disconcerted by finding the reader of the Paper utterly incompetent to impart his knowledge in an intelligible and business-like manner, and having no apparent grasp of his subject. This sort of thing only serves to bring the society into disrepute. Another curious habit seems to be that local members are expected to contribute their share to the general mass of knowledge, and are pressed, sometimes against their will, to read Papers which they themselves are perfectly conscious of not containing very important or original matter, being, perhaps, the "remainder biscuits" of other Papers read on previous occasions, or before other societies.

Could the Association be reorganised in order to bring more into prominence its salient and social qualities, advantage would probably accrue to all therein concerned. Means of communication are now so enormously facilitated that one of the original aims of the institution is to some extent unnecessary. But were its potential uses more seriously taken into consideration it would have been less possible as in the present instance, for a large number of the local professors to fail with such unanimity in their duties, and to show such lamentable want of interest in the whole proceedings as to desert the town, dismally signalling their departure by the sheets of brown paper and domestic directions decorating their windows, leaving only persons but indirectly connected with the work of the Association to show hospitality to its members. The mechanism and organisation of the British Association are not in any degree so good or so complicated as to make remodelling undesirable; and no one taking into consideration the value of the work done could doubt the wisdom of its members were they honestly to face the position of their body in the scientific world, and having come to some conclusion boldly to assert its right to exist, either by improving it as a practical working body, by making its work more serious, and its dilettante members less welcome; or by resting its value candidly on the, perhaps, not less useful standpoint of social intercourse. With some such remodelment as this there would be no danger of the summer meetings coming to an end. For the desire of hearing something new springs eternal in the human breast; and those workers who are enthusiasts and whose pleasure lies largely within their work, or in subjects bearing on their studies, would have the attraction of a holiday which combined a necessary change of air with an opportunity of interchanging stimulating ideas with their contemporaries.

GEARING.

BY E. TREMLETT CARTER.

In this series of articles the term "gearing" will be applied to all those combinations of mechanical parts which are intercepted between a motor, such as a steam engine or electromotor, and the work it has to do. The necessity for such mechanism arises from the unsuitability of the engine to being directly applied to the machine which has to do the work; either on account of their differences of speed, or because of the inconvenient position of the machine, or on account of the necessity to subdivide the power of the engine so that it may drive more than one machine. In the case of an engine driving a single dynamo the necessity for gearing arises from a species of incompatibility between the two; and since it is both expensive and wasteful of power it is to be avoided wherever possible. Gearing, therefore, must be looked upon as an evil by generating station engineers, an evil which should be eliminated by adapting the designs of engines and dynamos so that they will run together without it. But there are many cases in which an electrical engineer is compelled to use some form of gearing; in tramway work, in lighting installations run from a factory engine or countershaft, and in temporary work; and it may be of some use to discuss the relative merits, and to give some simple rules for designing the ordinary forms of gearing.

Gearing may be conveniently classified under two heads:—(1) Force-closure gearing, in which the power is transmitted through machine parts held in relative position by friction; and (2) pair-closure gearing, in which the parts are held together by the strength or molecular resistances of interlocked pieces. The relative merits of these two forms of gearing may be summed up in a few words. Friction, or force-closure gear, is very smooth running, silent, free from vibration, and has a tendency to destroy any severe shocks developed in the engine; as, when any such shock occurs, slipping takes place and the machine is almost unaffected; but it does not maintain a constant velocity-ratio between the engine and the machine, and on this account cannot be used where very accurate motions have to be transmitted. Moreover, owing to its tendency to slipping, and inability to prevent the machine driving the engine backwards, it cannot be used in such cases as tramway work, or for elevators. Pair-closure gear possesses the exact opposite of all these qualities; it is noisy and full of unpleasant vibrations; it cannot slip, and every irregularity of the engine is transmitted unaltered to the machine.

Belting.

Belting is a common form of friction gear. A strap or flat belt is passed over the flat or slightly convex faces of two pulleys, placed one on each shaft, and called the driver and follower respectively. Owing to the weight of the belt and the small sag that is allowed in the free portions, the belt, when not

Digitized by Google

running, is under a considerable tension, which has practically the same value in every part. This tension causes a pressure of the belt on every part of the arcs of contact with the pulleys, and this pressure causes everywhere a frictional resistance to slipping of the belt on the pulleys, which is equal to product of the pressure into the coefficient of friction between the belt and the metal of the rims. Now the pressure of the belt on the pulleys is not the same at all parts of the arc of contact, so that the total frictional resistance must be obtained by integration. In Fig. 1 let $d\phi$ represent a small element of the angle of contact, T the tension in the belt at that part, R the

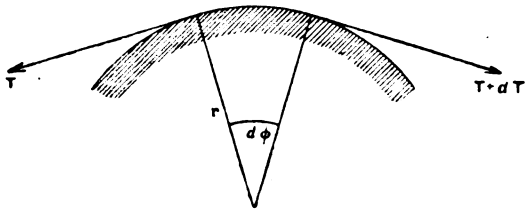

FIG. 1.

normal pressure on the element, and P the normal pressure per square inch on the element. Then, by the parallelogram of forces,

$$R = 2 \cdot T \cdot \sin \cdot \frac{d\phi}{2} = T \cdot d\phi,$$

also $$R = P \cdot b \cdot r \cdot d\phi,$$

where b and r are the breadth of the belt and the radius of the arc respectively. Therefore,

$$P \cdot b \cdot r \cdot d\phi = T \cdot d\phi,$$

$$P = \frac{T}{r \cdot b}.$$

If this normal pressure is multiplied by the coefficient of friction μ, the frictional resistance per square inch of belt at this point will be obtained; and this again multiplied by the surface of the element, $b \cdot r \cdot d\phi$, will give the actual frictional resistance of this element. Now, this resistance will oppose a difference in tensions between the two ends of the element which will be equal to the frictional grip of the element. Calling the difference in tensions which can thus be set up without slipping taking place, dT, we then have

$$dT = \mu \cdot P \cdot b \cdot r \cdot d\phi = \mu \cdot T \cdot d\phi,$$

whence integrating we get

$$\int_{T_1}^{T_2} \frac{dT}{T} = \mu \cdot \int_{0}^{\phi} d\phi.$$

$$\therefore \log_{\epsilon} \frac{T_2}{T_1} = \mu \cdot \phi,$$

or $$\frac{T_2}{T_1} = \epsilon^{\mu\phi}.$$

This gives the ratio between the tight and slack tensions, T_2 and T_1, which may be applied at opposite ends of the arc of

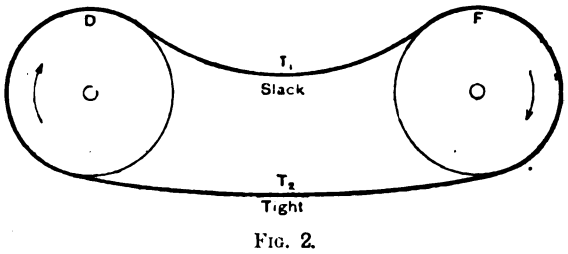

FIG. 2.

contact before slipping can occur. It will be seen that a large arc of contact and a high coefficient of friction are desirable.

In Fig. 2, let D be the driving pulley and F the following pulley. Suppose F clamped so that it cannot move, and a torque applied to D, then D will turn round, and as it does so it will increase the tension on one side and reduce it on the other side of the free belt. This difference in tension will cause a torque to be applied to F equal to

$$(T_2 - T_1) \times \text{radius of F.}$$

When T_2 is in the ratio of T_1 indicated by the exponential formula, the belt will slip on that pulley on which it has the smallest arc of contact. Suppose, however, that the torsional resistance of F is not sufficient to allow the tensions to exceed these limits, then the difference in tensions will go on increasing till the torque set up on F is equal to the torsional resistance which it opposes; at this point F will commence to turn and power will be transmitted from D to F. The amount of power transmitted will be,

$$\text{H.P.} = \frac{(T_2 - T_1)\,V}{33{,}000}.$$

Where V is the velocity of the belt in feet per minute.

The material most commonly used for flat belting is leather; although canvas and rubber, cotton, and even paper pulp have been employed. We can afford space, however, to consider only ordinary solid leather belting. On turned cast-iron or wrought-iron pulleys this material has a coefficient of friction of about 0·4 if not oily, but when the belt is allowed to get oily this is reduced to about 0·2 or 0·3. The arc of contact depends on the relative diameters of the pulleys, on their centre distance, on the tightness of the belt, and whether it is crossed or open, as well as on the direction of driving. It is always advisable, where possible, to drive with the tight part of the belt on the lower side, as shown in Fig. 2, for this makes the slack part sit down on the pulleys, and thus increases the arcs of contact. Crossed belts should be avoided where steady driving is necessary, and are only to be employed where reversed motions are required. With open belts at the proper centre distance between pulleys, the ratio of working tensions may safely be raised to 2, the rule being to make the arc of contact on the smaller pulley *not less* than 40 per cent. of its circumference.

The safe stress per square inch of solid leather belt, allowing for reduction of strength due to lacing, rivetting or cementing, may be taken at 320lb., and this is equal to a maximum tension of 20lb. per inch width for every sixteenth of an inch thickness. With these data we may proceed to design the belt to transmit a given horse power:

$$(T_2 - T_1)V = 33{,}000 \text{ H.P.}$$

And $$T_1 = \tfrac{1}{2} T_2$$

Whence, $$T_2 = \frac{66{,}000 \text{ H.P.}}{V}$$

Also, $$T_2 = 320 . b . t$$

where b and t are the breadth and thickness in inches. Consequently, $$b \cdot t = \frac{206{\cdot}25 \text{ H.P.}}{V}$$

The proportion between b and t will be decided by the considerations that if the belt is made very thick much power is wasted in continually bending fresh portions of it over the pulleys, while if it is too thin and wide the pulleys will be large, heavy, and expensive. The waste of power on account of the stiffness of the belt varies as the square of its thickness and as its breadth. Belts of moderate size are usually from 16 to 25 times their thickness in width. As to the best value for the velocity of the belt, it must be remembered that too low a speed will entail a heavy and expensive belt, while too high a speed will increase the loss of power and the depreciation, and will put an unnecessary strain on the belt on account of centrifugal action. There is a certain speed at which it is most economical to work a leather belt, and that speed lies somewhere between 2,500 and 3,000ft. per minute. The latter is a very common figure for machine belts, while engine belts are usually run slower. Slow-speed engines of moderate power often run belts as slowly as 1,000ft. per minute, owing to the fact that a higher speed would involve too large a diameter of pulley; but these excessively low speeds are not to be recommended. With very large power to be transmitted, the belt becomes so thick and wide that it is a serious source of loss of power. It is not well to use leather belting for dynamo work

Digitized by Google

where more than 80 or 100 H.P. is to be transmitted. In such cases ropes are more economical of power, though they take up more floor space. The saving in power more than compensates for the extra cost of floor space.

The ratios of tensions given in the above table indicate the points at which the tensions are sufficient to cause continual slipping of the belt over the pulley; in practice, the ratio of tensions in a belt should not exceed 60 per cent. of the figure supplied by the table. The following table gives the amount of horse-power transmitted by one square inch section of solid leather belt under these safe conditions, when running at 1,000 feet per minute:—

Table *giving the Horse-power Transmitted per square inch Section of Solid Leather Belting at 1,000ft. per minute, with Different Arcs of Contact and Different Amounts of Friction.*

Values of ϕ in degrees.	Values of μ.							
	0·15	0·20	0·25	0·30	0·35	0·40	0·45	0·50
	Horse-power per square inch of section of belt.							
90	1·2	1·6	1·9	2·3	2·5	2·8	3·1	3·2
100	1·3	1·7	2·0	2·4	2·6	2·9	3·2	3·4

120	1·6	1·9	2·3	2·6	2·9	3·2	3·5	3·8
130	1·7	2·1	2·5	2·8	3·2	3·5	3·7	4·0
140	1·8	2·3	2·7	2·9	3·4	3·7	3·9	4·1
150	1·9	2·4	2·8	3·1	3·5	3·8	4·1	4·3
160	2·0	2·5	2·9	3·4	3·7	4·0	4·2	4·4
170	2·1	2·6	3·1	3·5	3·8	4·1	4·3	4·5
180	2·2	2·8	3·2	3·6	3·9	4·2	4·4	4·6
190	2·3	2·9	3·3	3·7	4·0	4·3	4·6	4·7
200	2·4	3·0	3·5	3·9	4·2	4·4	4·7	4·9

The above table is correct for velocities between 1,000 and 4,000 feet per minute if the following rule is adopted: Multiply the figure given in the table by the section of the belt in square inches, and by the velocity of the belt in feet per minute, and divide by 1,000; the result is the horse-power transmitted by the belt. To find the section of belt required to transmit any given horse-power, multiply the horse-power by 1,000 and divide by the product of the velocity of the belt into the figure given by the table; the result is the section in square inches.

Belt joints for electric-light work must be carefully made, with a view to strength and uniform running over the dynamo pulley. The ends should always be cut off square with a sharp knife, using a set-square, and not guessing with the eye. The holes should be carefully and cleanly punched out with a small round punch, and not wriggled out irregularly with a bradawl, or they will be liable to be torn by the rivets. The joints are either rivetted, laced, or cemented, the ends being lapped over one another, or fastened by means of a cover strap of leather of the same thickness and width as the belt, and about 15in. to 18in. long. The butt joint, with a cover strap, works more smoothly than an ordinary lap-joint; but the best joint is made by scarfing the ends of belt to a gentle taper, cementing them into a lap-joint of uniform thickness, and rivetting through with countersunk-headed copper rivets, at the rate of one rivet per 4 square inches of lap. Unfortunately this joint cannot be taken apart in order to shorten the belt when it has slacked out with wear; and it is thus necessary to have one joint of the ordinary butt-strap form. Rivets should be distributed over the strap at the rate of $2\frac{1}{2}$ to 3 square inches per rivet. The slack which develops in a belt soon after it is put on the pulleys is usually "taken up" by means of rails, the dynamo being moved along these rails, so as to tighten the belt, by means of screws. When a lot of slack has thus accumulated it is usually cut out of the belt at one of the joints, and the dynamo run forward to the front end of the rails again. It is always well to examine belt joints a short time before commencing to run the machinery. "A stitch in time saves nine," and a little attention before starting will often save the inconvenience and disappointment of a breakdown when the machinery is most required.

Belt pulleys are usually of turned cast-iron or wrought-iron plate; but for high-speed belting cast steel pulleys must be used. The face of cast-iron pulleys is convex, having a radius of curvature of about four times the width; wrought-iron pulleys are sometimes formed of dished plate, so as to give the face this curvature, but are more commonly flat. The advantage of the curvature is that it helps the belt to ride on to the middle of the pulley face if it should get displaced towards the edge, and thus tends to prevent the belt slipping off the pulley. Cast-iron pulleys are heavier than wrought-iron, but run with truer surfaces, owing to the fact that they are turned up to centre after casting. Cast iron is, however, a very unreliable metal under the stresses to which pulleys are subjected, and must on no account be run with a higher rim-velocity than 80ft. per second. Pulleys and other machine details of this metal should on no account be hammered, as it is very brittle. The arms of cast-iron pulleys are usually a single or double curve, with gradual contraction of section from the point where they join the rim. The object of these elements of design is to reduce the internal stresses which are set up when the metal cools after casting. Sudden contraction of section, sharp angles, and straight spokes, or arms, are always to be avoided in iron castings. Wrought-iron pulleys are tougher and less liable to fly to pieces than cast-iron. The rivets are the weakest parts as a rule, and when a wrought-iron pulley bursts it gives out at the joints, but is still held by the shaft. When the peripheral velocity is very high, belt pulleys are found to work more satisfactorily if the face is perforated with a number of small circular holes. This enables the belt to get a firmer grip of the pulley, as the film of air which otherwise separates the former from the latter is able to escape through these holes.

The diameter of the pulley is chosen with respect to the speed of the belt, and the number of revolutions per minute required on the shaft. If the belt speed is divided by the revolutions required, the quotient is the circumference of the pulley. It is not usual to make any correction for the thickness of the belt, except when the pulley diameter is not very large in comparison. If this correction is desirable, the real diameter of the pulley can be obtained from the rough rule given above, by subtracting the belt thickness from the diameter which that rule gives. The pulley width is best calculated from the following equation:—

$$w = 1\tfrac{1}{3}\ (b + \tfrac{1}{2}),$$

Where w is the width in inches, and b the breadth of the belt.

The centre distance between pulleys should be selected with a view to getting a good arc of contact on each pulley, and a weight of belt freely suspended sufficient to give the requisite tension in the belt. When a large pulley drives a very small one, therefore, the centre distance should be greater than in the case of two pulleys of equal size. When the portions of the belt between pulleys are freely suspended, it is not advisable to allow a less distance than 10ft. between centres, while it will generally be found necessary to have at least 15ft. for steady driving with pulleys of nearly the same size, or when one is not less than one-quarter the other, and from 15ft. to 20ft. when there is a greater difference between the diameters. Where it is necessary to have a compact plant, and such long centre distances are out of the question, if belting is to be used (though it would be better to adopt some other form of gear), jockey

Digitized by Google

pulleys must be used. These are idle pulleys, so placed that they force the belt to make a large arc of contact on the pulleys even with the minimum of space between the pulleys. Fig. 3 shows an arrangement of jockey pulleys as used for a ship lighting plant. The slack can be taken up by turning a handle which causes the jockey pulleys to approach one another.

Example.—*A dynamo requiring 50 H.P. at 400 revolutions per minute has to be run from a line of countershafting making 200 revolutions per minute. Design the belt gearing.*

Roughly estimating we find that with ordinary velocities of belt the diameter of the dynamo pulley would be about two feet. We take this figure, and find that the belt velocity will be 2,514ft. per minute. The diameter of the pulley on the countershaft will be 4ft. The maximum tension on the belt when running will be 1,320lb. Taking solid leather belting at 320lb. per square inch working tension, the section of the belt works out to $4\frac{1}{8}$ sq. in. Owing to the small diameter of the dynamo pulley we should hesitate to put on a belt of greater thickness than $\frac{5}{16}$in., which gives a width of $13\frac{1}{4}$in. If this seems too wide, we might take the smallest thickness of double belting—though the pulley is rather too small for it—and the size of belt would then work out to 11in. wide and $\frac{3}{8}$in. thick. The choice lies between a wide belt $13\frac{1}{4}$ by $\frac{5}{16}$ and a thick one 11 by $\frac{3}{8}$in.

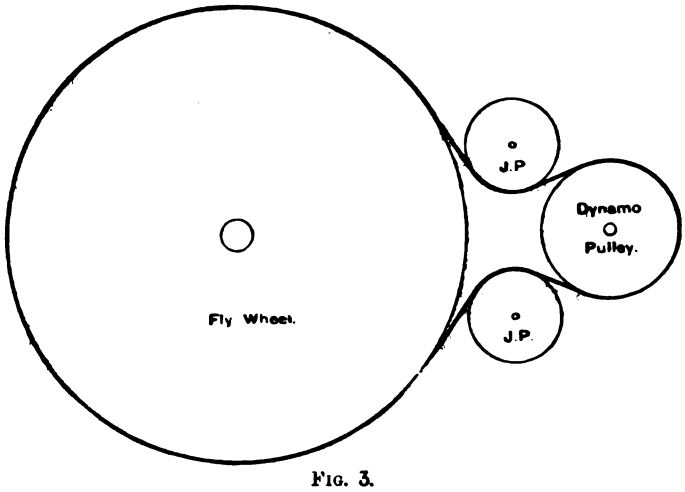

Fig. 3.

It would be advisable to have a centre distance not less than 15ft.

(To be continued.)

A CONTRIBUTION TO THE THEORY OF THE PERFECT INFLUENCE MACHINE.*

BY J. GRAY, B.SC.

The history of the development of the heat engine appears to have repeated itself very closely in that of the electrical influence machine. The early experimental gropings of Savary and Newcomen with the steam engine run parallel with those of Darwin, Nicholson, and others with the influence machine, resulting, in both cases, in machines certain, indeed, in their action, but, from ignorance of principles, very inefficient in their design. A close study of the working of the steam engine and the application of higher principles by the genius of James Watt produced a machine of much greater efficiency, and left little to be done by his successors except the perfecting of details, till another great advance was made in the theory of the heat engine. The labours of Holtz, extending over a period of twenty years, during which he worked out and perfected in detail almost all the leading types now in use, have earned for him a good claim to be considered the Watt of the electrical influence machine. The third stage in the development of the heat engine coincides with the rise in the science of thermodynamics. The investigations of Carnot, Thomson, Rankine and others showed that the heat cycle through which a mass of working fluid must pass in order to give a maximum efficiency must be represented by adiabatic and isothermal lines only. This principle has been applied to the influence machine by Maxwell, who showed that equiquantic and equipotential lines must form in this machine the perfect cycle.

The object of this Paper is to describe some graphic methods which I think help to elucidate the action of Maxwell's machine, and also to show by what amount the efficiency of the influence machine may be increased by the application of Maxwell's principles.

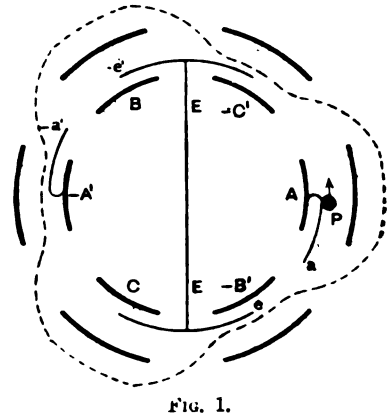

Fig. 1.

Maxwell points out that, over and above the loss from leakage, there is a loss of energy through the sparking which takes place just before a carrier makes contact with the charging or discharging points in its course. The energy lost in each spark is $\frac{1}{2}$ Q V; Q being the quantity of electricity transferred, and V the difference of potential producing the spark. The object of his invention is to do away with sparking. He effects this by causing the carrier of electricity to make contact with charging and discharging springs when its potential is the same as that of the spring in question, and to remain in contact during the whole time of charge or discharge.

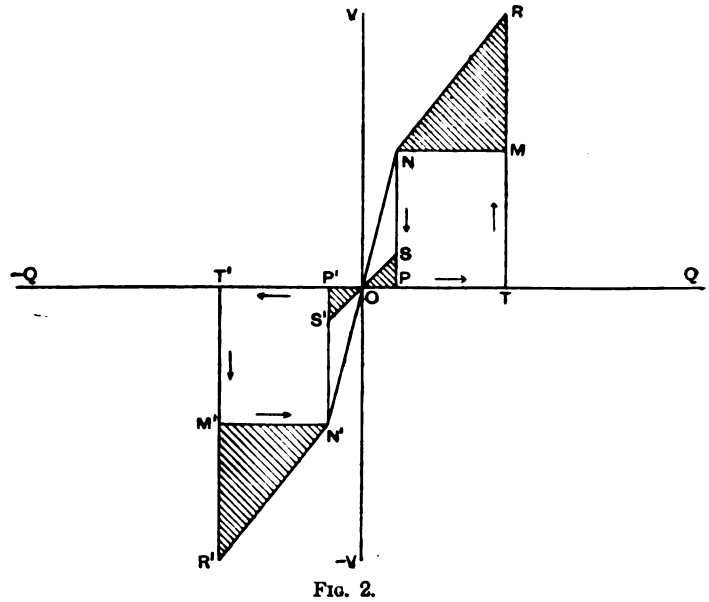

Fig. 2.

Fig. 1 is a diagram which will serve to show the action of Maxwell's machine. In this diagram conductors are represented by black lines, &c., and insulators are left white; a convention in agreement with the electromagnetic theory of light, according to which these bodies are respectively opaque and transparent. The machine consists of six fixed hollow conductors, A, B, C, A', B', C', which may be looked upon as six sections of a hollow anchor ring, separated by insulating air spaces. A conducting carrier P is caused to revolve through the centre of the hollow conductors in the direction shown by the arrow. Three of the

* Paper read before the British Association, in Section A, Edinburgh, August, 1892.

Digitized by Google

conductors A B C are connected to a Leyden jar of large capacity charged to a positive potential V; the other three conductors A′, B′, C′ are connected to another similar Leyden jar charged to a negative potential – V.

The conductors taken in order round the ring are thus alternately positive and negative. The dotted line on the diagram is drawn to represent approximately the potential at each point of the circular path through the centre of the conductors along which the carrier P travels. The potential at each point is indicated by the distance of the dotted line from the outer circle of the diagram. To the conductors A and A′ are connected contact springs a and a'; and lying partly inside the conductors B and C′ is a spring e' connected to earth, or a similar spring e lying partly within the conductors B′ and C.

The changes in the energy of the carrier P during one complete revolution and the work done upon it, I propose to show by a Q V diagram, *i.e.* an energy or work diagram, in which the components are the quantity and the potential of the carrier. Let Q O Q, V O V (Fig 2) be the axes of co-ordinates; distances along O Q representing quantities of electricity on the carrier, and distances along O V representing potentials of the carrier. We shall start with the carrier P as represented in Fig. 1, just about to break contact with the spring a which is connected to the conductor A. The potential of the carrier will be equal to that of A, which we will represent by an ordinate P N (Fig. 2). Its quantity, due to its not being completely surrounded by the conductor A, may be represented by O P. As O P = V tan P N O, tan P N O will represent the capacity of P with reference to the earth. Let tan P N O = α. The point N on Fig. 2 corresponds therefore to the position of P on Fig. 1. In passing from its initial position till it comes in contact with the earth spring e' inside the conductor C′, P retains its quantity unchanged. We will suppose that S P represents the potential of P when about to make contact with the earth spring, if the conductor C′ were removed. In order to reduce the potential of P to zero when it makes contact, the inductive effect of C′ must be such as to produce an equal and opposite quantity to O P on the carrier P. Therefore,

$$C' = \frac{O P}{V} = \frac{\alpha V}{V} = \alpha$$

is the equation for determining C′, the coefficient of induction of the conductor C′ upon the carrier P.

The state of the carrier is now represented by the point P on Fig. 2. The passage of the carrier along the spring e' is represented on Fig. 2 by the line P T′, corresponding to a gradual loss of electricity at zero potential till it finally leaves the spring with a negative charge represented by O T′. From contact with the spring e' to contact with the spring a' the quantity remains constant but the potential falls, *i.e.* we pass from T′ to M′ on Fig. 2. Along the spring a' the quantity increases positively (or decreases negatively) at constant potential – V; *i.e.* passes from M′ to N′ on fig. 2. The spring a', of course, must be of such a length as to meet the carrier when it is at the same potential as A′. This completes one half of a revolution, and the other half is exactly similar though opposite, namely along N′ P′ T M N to the starting point.

The work done on the carrier in one revolution is equal to twice the area of the rectangle N T. A quantity P T of positive electricity is imparted to the conductor A, and an equal quantity of negative to the conductor A′, the potentials being V and – V respectively.

The efficiency of the machine in such a cycle is *unity*, that is to say there is no loss, supposing friction, leakage, &c. to be absent. The quantity of electricity produced per revolution is less than the maximum possible by the amount left on P when it leaves the discharging conductors A or A′. The conductors C and C′ are called by Maxwell regenerators, because their function is similar to the regenerator in the heat engine.

Let us now in the first place consider how much the efficiency of the machine is reduced by the removal of the regenerators. The effect of removing C′ will be to allow the carrier P to spark to the spring e' before making contact, and the energy dissipated in this spark is equal to the area of the triangle S P O, if the inductive effect of A and B on P is negligible. There is a similar loss in the other half of the revolution. The efficiency will now be

$$E = \frac{Q V}{Q V + \frac{1}{2}\alpha V . S P.} = \frac{Q}{Q + \frac{1}{2}\alpha S P}$$

This efficiency approaches to unity as α or S P approaches zero, and α can always be made very small by extending the discharging conductor and bringing it very close to the carrier.

Let us now, in the second place, consider the loss of efficiency due to replacing the long contact springs a and a' by contact points inside the conductors A and A′. On approaching and entering A the potential of P will not stop at M (fig. 2), but will rise to R before discharge. If α is very small, and the conductors B′ and A similar and equal, M R will be very nearly equal to M T. The energy dissipated in the spark is equal to the area of the triangle R M N. The efficiency in this case would be—

$$E = \frac{1}{1\frac{1}{2}} = \frac{2}{3}.$$

The absence of long contacts in the discharges thus leads to a much greater loss of efficiency than the absence of the regenerators.

Thirdly, if the long contacts e and e' are replaced by point contacts at the centres of the conductors B and B′, the energy dissipated per cycle is equal to the area of the triangle P N T′. The efficiency

$$E = \frac{1}{1\frac{1}{2} + \frac{\alpha V}{Q}} < \frac{2}{3}$$

Finally, when all the contacts are points, as in the ordinary influence machine, the efficiency,

$$E = \frac{1}{2 + \frac{\alpha V}{Q}} < \frac{1}{2}$$

All these results can be obtained readily by inspection from the diagram Fig. 2.

I have made a machine with long contacts but without regenerators, which is self-exciting, and gives considerable quantity; but owing to difficulties of insulation, which I hope soon to overcome, I have not been able to get long sparks. These graphic methods may be applied to any influence machine for investigating their theoretical efficiency.

ON PRIMARY AND SECONDARY BATTERIES IN WHICH THE ELECTROLYTE IS A GAS.*

BY PROF. ARTHUR SCHUSTER, F.R.S.

If a current of electricity passes through a vessel which is partially exhausted the whole gas contained in the vessel becomes a conductor in the ordinary sense, and a single cell will send a measurable current through it. This phenomenon, which may conveniently be called "secondary conduction," has been investigated by the author and Prof. Arrhenius. A more detailed study during the past year has brought some interesting phenomena to light. If the secondary electrodes are platinum and the gas is a hydrocarbon, phenomena of polarisation are observed exactly similar to those found when water is decomposed. The electromotive force of polarisation in that case amounts to about 3 or 4 volts. No polarisation or traces only are found with hydrogen, oxygen, nitrogen, cyanogen, aqueous vapour, ammonia, and other gases experimented upon; but phosphoretted hydrogen shows the phenomenon. When the electrodes are made of copper or iron no polarisation is observed in hydro-carbons; on the other hand, when aluminium or magnesium are used, it rises to very high values. Magnesium electrodes, in which the secondary current from 30 Clark cells was allowed to pass for some time, showed a polarisation of 35 volts. The polarisation effects are

* Abstract of a Paper read before the British Association in Section A Edinburgh, August, 1892.

Digitized by Google

studied just as in the case of liquids by interrupting the polarising current and connecting the secondary electrodes with a galvanometer or electrometer. When a hydrocarbon is used both electrodes become covered with a thin film, which shows the colours of thin layers of metallic oxides or sulphites. The fact that the electromotive force depends so much on the nature of the metal tends to show that a metallic carbon compound is formed by the action of the primary current, and that the effects are analogous to those of the secondary battery.

The author has also studied the currents observed when electrodes of different metals are inserted into a gas rendered sensitive by the electric discharge. Arrhenius had already shown that zinc and platinum in air give a permanent difference of potential under these circumstances. The author finds that whatever the gas which has been converted into a conductor by a primary discharge, permanent currents may be obtained from magnesium and platinum electrodes, the magnesium always being electro-negative. The electromotive force is, however, different in different gases, and higher for instance in oxygen than in hydrogen.

ON CERTAIN VOLUME EFFECTS OF MAGNETISATION.*

BY PROF. CARGILL G. KNOTT, D.SC., F.R.S.E.

The experiments had to do with the changes of the internal capacity of five iron and five steel tubes, each set having been cut from the same bar and bored to various bores. All had the same length, 18in., and the same external diameter, 1½in. The iron tubes were distinguished by the Roman numerals I. to V.; and the steel tubes by the corresponding Indian numerals 1 to 5. Tubes of the same number had equal bores. Thus the internal diameter of Nos. I. and 1 was 1¼in.; of Nos. II. and 2, 1in.; and so on to Nos. V. and 5, which had each an internal diameter of ¼in. Each tube was closed below. When set up for experiment it was closed above by a screw nut through which a capillary glass tube passed, and was then placed vertically in the heart of the magnetising coil. The whole of the metal tube and part of the capillary were filled with water, and the changes of internal volume were measured by the motion of the liquid meniscus in the capillary. In strong fields this motion was easily seen by the naked eye. It was shown at the meeting projected by the lantern on the screen. The measurements were made by means of a micrometer microscope.

The observed changes of volume amounted in some cases to nearly 5×10^{-4} cubic centimetres; and in the narrower-bored and thicker-walled tubes it was evident that higher fields than those used would have produced still greater volume changes. The highest field that could be safely used was 1,400 C.-G.-S. units.

The general characteristics may be briefly described thus. In Nos. I., 1 and 2, the effects were very similar, differing only in detail. In low fields the capacity was diminished, in high fields increased. In other words, the graph showing the relation between magnetising force and change of volume began by passing under the line of zero change, then crossed it and continued thereafter above it. In Nos. II. and III. a similar *form* of graph was obtained, only it did not reach the zero line after the maximum decrease was passed. In these cases, as in the case of No. IV., the capacity was always diminished. No. 3 showed increase of capacity in all fields from the lowest to the highest. Nos. 4 and 5 began by showing increase in low fields, but in fields higher than 200 units showed decrease of capacity. A similar but less marked effect was obtained with No. V.; in other words, the graphs of Nos. 4, 5 and V. passed first above the zero line, then cut through it, and passed in almost rectilinear course below it, continuing so to the highest fields attained. The following scheme gives the nature of these changes, *minus* meaning a diminution of bore, *i.e.*, an average contraction of the walls of the tube as a whole, and *plus* an increase of bore or average expansion. By low fields we mean fields of less than 200 units. The numbers are the greatest measured values of the dilatations, or changes per unit volume, and are maximum or minimum values in all the low fields except in the case of No. 3 and No. IV.

Increase of Capacity (in 10^{-5} cubic cm.) of Iron and Steel Tubes.

—	Iron tubes.		—	Steel tubes.	
Nos.	Low field.	High field.	Nos.	Low field.	High field.
I.	−17	+11	1	−19	+42
II.	−19	− 6	2	−12	+15
III.	−25	−26	3	+12	+40
IV.	−14	−51	4	+2·4	−41
V.	+0·5	−32	5	+2·3	−13

The greatest *change per unit volume* was obtained in the case of tube 4. In field 1,000 the dilatation amounted to -4×10^{-6}.

It was necessary to subject the tube to each magnetic field taken first in one direction and then in the other. If this precaution were not taken, the material got into a state of magnetic bias. Very interesting results were obtained when a smaller field was applied after a greater field, the magnetic bias, or "after-effect," due to the larger field having a very pronounced influence. To get rid of this magnetic bias it was sufficient to neutralise the tube by subjecting it to a series of fields of diminishing intensity and alternating direction.

ON THE DIELECTRIC OF CONDENSERS.*

BY W. H. PREECE, F.R.S.

Artificial cables are very useful adjuncts to the laboratory of the telegraph engineer. They not only enable him to experiment at his leisure, but they form very useful means to test and compare high-speed and delicate telegraph apparatus, and especially telephones. I have one, made some years ago, which has been in incessant use, composed of 54 inductionless coils of insulated copper wire, each giving 33 ohms resistance, and having a condenser of 1 microfarad capacity at the juncture of each pair of coils, and one at the termination of the series. This represented a circuit of a total capacity (K) of 54 microfarads, and of a total resistance (R) of 1,782 ohms, the K R being 96,228. This was equivalent to an ordinary submarine cable of 162 nauts length. It was not sufficient for our growing wants; and another similar set was recently made, but it did not give the same results. The resistances were exactly the same, but the individual capacities differed. This difference of about 5 per cent. was, of itself, of no practical consequence for the particular purpose for which the cable was constructed; but on carefully comparing the two "cables" with telephones it was found that with the same nominal K R the one gave 30 per cent. better results than the other. This was a surprising and unexpected result. I thought it might be due to inductance, but none, neither *self* or *mutual*, could be detected.

The insulation, taken after one minute's electrification, of each was:—Old cable, 172·8 megohms per naut; new cable, 82·8 megohms per naut, so that the difference was in favour of the old one. But the electrification of the new one was much less than that of the old one. The difference in the reading between the first and second minutes on the former was $\frac{1}{20}$th of that of the latter.

Each cable was then rapidly charged and discharged 1,200 times, at varying rates, with an E.M.F. of 40 volts, and the cumulative remaining charge in each case read by deflection on

* Abstract of a Paper read before the British Association in Section A, Edinburgh, August, 1892.

* Paper read before the British Association in Section A, Edinburgh, 1892. Lord Kelvin proposes to call this useful instrument a "Leyden," because the term "condenser" is applied to other more appropriate mechanical and physical apparatus.

Digitized by Google

a Thomson galvanometer. This was done by passing a 10ft. length of perforated slip through a Wheatstone's automatic transmitter. The following are the results :—

Number of discharges per second.	Discharge.		Percentage difference.
	New.	Old.	
20	46	28	39
40	86	55	36
80	151	100	33
120	200	136	32
160	237	168	29

This clearly shows that the effect is due to absorption. Electrification, polarisation, and absorption, are phases of electrolytic work done by the current upon the dielectric. The material itself, or the impurities contained in it, being slightly decomposed by the leakage current, a counter E.M.F. is set up, which increases the apparent resistance (electrification), it gives a current of discharge reverse to that of charge (polarisation); it absorbs a quantity of electricity, the undissipated part of which is recovered as a discharge current. The condenser acts, in fact, like a secondary cell.

We are now using better paper than formerly—that made from the best linen rags, thinner tinfoil, and better wax, the best refined unadulterated white paraffin, having a melting point of from 125°F. to 128°F. Resin was formerly mixed with the wax, and when hot and liquid it was painted on the paper with a brush. The paper is now thoroughly dried and well saturated with wax by soaking under pressure, so as to get rid of all the moisture. Hence there is less electrification and less absorption, and hence the difference." In the old type of condenser we observed a variation of capacity due to temperature, but in the new type this has disappeared. This effect of absorption on the effective capacity of the condensers and of insulated conductors is new to me; and as it may be new to many others, I have thought it to be of sufficient interest to bring it before Section A.

It is a new term to be added to the equation of energy of compound circuits, and it has evidently a material influence upon the retardation of signals in long submarine cables. It has an equally important influence on the efficiency of telephone circuits, and it accounts partially for the great difference in my K R law between the observed effects of aerial and those of subterranean or submarine conductors. The former are always much superior to the latter. This would be due to the absence of polarisation in air, as well as to other electromagnetic and electrostatic causes. No work would be done on the molecules of air, no energy would, therefore, be absorbed, and no retardation of currents from this cause would ensue. An air dielectric is clearly the "Holy Grail" of the electrician.

ON THE EARTH-CURRENT STORMS OF 1892.*

BY W. H. PREECE, F.R.S.

The year 1892 has been remarkable in the number and severity of those electric storms which interfere so seriously with telegraphic communication. Unfortunately, observations made upon them on working circuits are rarely reliable. Their arrival and departure are sudden, they come when they are least expected, and they occur in busy hours, when the wires are fully occupied with more remunerative currents, and when the staff is fully engaged. Their presence, duration, and relative intensity are so exactly coincident with magnetic disturbances that the recorded observations in magnetic observatories of needle variations may be taken to indicate the same elements of earth currents also, but they do not give their direction nor their absolute intensity. Their general direction is determined by the simultaneous observation of many circuits running in many directions, and noting the lines of maximum and those of no disturbance. This gives the position of the equipotential planes on the surface of the earth, and the intensity of the currents gives the difference of potential between these planes.

I have not succeeded in obtaining definite facts to prove that these planes are perpendicular to the line joining the centre of the earth and the centre of the sun; but there is little doubt that it is so, for telegraph circuits running in this direction experience the maximum disturbances, while those running at right angles on the equipotential planes suffer no disturbance. Those that experience the maximum disturbance in the forenoon are not affected in the evening, and *vice versâ*.

The storms commenced on January 4th, and they have been observed at frequent intervals since. The great storms occurred on February 13th, March 12th, April 24th and 27th, May 18th, and July 16th. The intensity of the maximum currents observed frequently exceeded 0·045 ampere, or 45 milliamperes, which much exceeds in strength the working currents. Hence ordinary telegraph working was paralysed, and we had to resort to metallic circuits and to the use of condensers to maintain telegraphic communication. The effect of such currents on our railways might be positively dangerous, for they ring bells and reverse the block signals. A current of 0·045 ampere on an ordinary iron telegraph wire (No. 8), means 0·54 volt per mile, so that the equipotential planes differing by 1 volt would have been placed about two miles apart. These earth currents, though variable, are always continuous, and give no indication of alternations. The simultaneous appearance of Auroræ shows that disturbances on the sun's photosphere, as indicated by sun-spots, produce electrostatic and electromagnetic effects on the earth's surface of enormous magnitude.

The appearance of earth currents is invariably simultaneous over the whole globe. Observers abroad would benefit science if they would record the maximum strength, in milliamperes, of the currents received, the geographical direction of the terminal earths of the circuits affected and unaffected, the resistance, in ohms, of the circuits on which the currents are measured, and if they were to give the times of observation in Greenwich, and not in local time.

THE DESTRUCTION OF LIGHTNING PROTECTORS BY RECENT MUNICIPAL LEGISLATION.*

BY W. H. PREECE, F.R.S.

The immunity of private houses from being struck by lightning is very marked, and this is considered to be due to the fact that the lead on our roofs and the iron stack pipes that drain these roofs, connected as they are together, form admirable lightning protectors. Any charge of atmospheric electricity which may fall upon a house so protected is conveyed harmlessly away to the earth. Householders are now required to remove these pipes from direct connection with the drains, and to leave an air space between the end of the pipe and the grating of the drain. The result is that the electric conduction of the pipe is broken, the stack pipe ceases to be a lightning protector, and houses are left exposed to the dangers of atmospheric electricity.

The remedy is very simple. The pipe need not be entirely cut away; three-fourths of its circular section may be removed for the distance required and one-fourth may be left to maintain the old electrical connection, or if the separation has been effected, then the stack pipe should be connected with the drain by a wire or rod so as to restore a path for the charge to the earth.

Householders are also now compelled to put up stack pipes to ventilate their soil pipes, erecting above their roofs a metal tube forming a prominent object, exposed to the atmospheric charge and terminating frequently in an earthenware pipe on the first floor. They are thus liable to be struck by lightning without offering any means of escape. They should be connected electrically with the earth, either directly or indirectly, through the stack pipes, which would then make them sources of safety rather than of danger.

EXPERIMENTS ON ELECTRICAL RESISTANCE.*

BY DAWSON TURNER, M.D.

M. E. Branly has reported in the *Bulletin de la Société Internationale des Electriciens*, May 9th,† some experiments on the influence of currents of high potential upon electrical resistance. Some of these experiments have been repeated by the author. It is well known that metallic powders present a very great resistance. This can be lowered to an extraordinary degree by the passage of a spark in the neighbourhood. The author has tried amongst other substances, powdered aluminium, finely divided copper, annealed silenium, iron filings, small shot, mixtures of aluminium and resin fused into a solid stick, &c. The best results were obtained with the first two. A short glass tube is filled with powdered aluminium, and placed by means of copper wires passing through corks, in circuit with one or two cells and a galvanometer. The needle of the galvanometer will remain at zero. The resistance of the aluminium is very great. If a spark from an induction coil be passed in the vicinity, the resistance will become at once diminished, and the galvanometer needle will be deflected. Thus, though there was at first no appreciable current, there may now be one of 250 milliamperes. The powder will, if undisturbed, remain a conductor for some little time, but if the table be shaken or the glass tube be moved, the initial resistance at once returns and the needle passes back to zero. After the resistance has been once lowered in this way, the powder gets into a much more sensitive condition; a spark at a great distance lowers the resistance and the slightest jar restores it. The author was not successful with ordinary iron filings, perhaps because they were not sufficiently finely divided. More shaking does not restore the resistance of the solid stick of aluminium and resin, but the application of a little warmth does. These experiments would appear to suggest that the molecules become arranged in a definite order under the influence of a discharge, even though the latter occur at a considerable distance.

THE TEMPERATURE VARIATION OF THE MAGNETIC PERMEABILITY OF MAGNETITE.

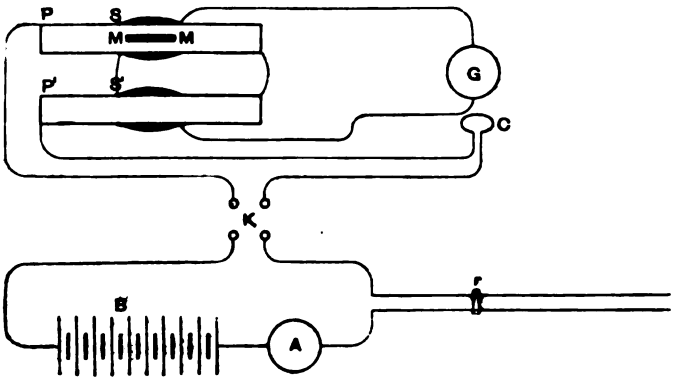
BY EDWIN H. BARTON, B.SC., AND W. WILLIAMS, B.SC.

After being engaged for some time upon the Magnetic Survey of the United Kingdom, Prof. Rücker put forward his Theory of Terrestrial Magnetism (*Proc.* Roy. Soc., Vol. XLVIII., June 19, 1890), "Relation between Magnetic Permeability of Rocks and Regional Disturbances." In connection with this theory it was desirable to ascertain the permeabilities of various rocks both at ordinary and high temperatures. The investigation referred to in the present preliminary Note is an instalment in this direction.

Prof. Rücker proposed this undertaking, and indicated the plan to be followed. It was then carried out under his supervision at the Royal College of Science, London (as follows:—W. Williams worked out the theory of the method, calculated what coils would be suitable, and wound them accordingly. E. H. Barton arranged the apparatus, eliminated disturbances, took the observations, and plotted the results.)

For measuring the susceptibility of the magnetite the ballistic method was adopted. Since the specimen was to be exposed to high temperatures, the coil to receive it was insulated with asbestos paper and wound upon a porcelain tube. The secondary coil was further insulated from the primary by two sheets of mica, to obviate the probability of leakage between the two. The temperature of the magnetite, when heated, was estimated from the consequent E.M.F. of a thermo-electric couple of platinum and osmium-iridium. One of the junctions was round the specimen of magnetite, and the other in a beaker of water. This couple was first calibrated by placing one junction in melting ice, boiling water, and sulphur vapour* respectively, the other junction being meanwhile at ordinary temperature. The arrangement adopted for obtaining the sulphur vapour and the temperature assigned to it were those published by Messrs. Callander and Griffiths in the *Proc.* Roy. Soc.*

The electrical connections used for measuring the induction effects are diagrammatically represented below (Fig. 1):—



M M, Specimen of magnetite. P and S, Primary and secondary coils which are heated (by gas stove not shown). P' and S', Compensating coils. B, Battery. A, Ammeter. r, Adjustable resistance. K, A "Pope's" commutator. C, Compensating coil. G, Highly sensitive low-resistance galvanometer.

FIG. 1.—Diagram of Electrical Connections for measuring the Induction Effects.

Eight distinct disturbances were dealt with. Some of them were eliminated; others measured, and the necessary correction applied when deducing the true effect due to induction.

The result obtained may be exhibited by a curve whose abscissæ are the temperature of the magnetite, and whose ordinates are proportional to the induction effects due to its presence, the impressed magnetic field being constant. Commencing at ordinary temperature, it is seen from the curve (Fig. 2) that the susceptibility for the specimen used rose

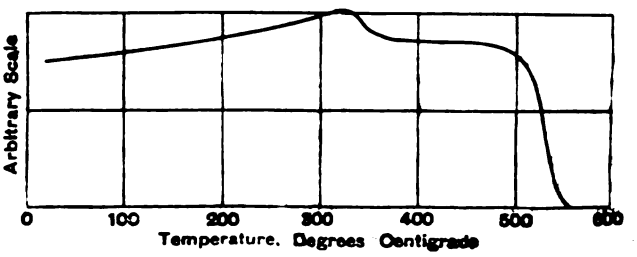


FIG. 2.—Curve showing the Variation of the Magnetic Susceptibility of Magnetite with Temperature, the impressed magnetic field being constant.

gradually at first with increase of temperature, reached a maximum at 325°C., then fell away to zero at 557°C. The sharp peak in the curve at 325°C., though apparently anomalous, was confirmed by careful repetition of the measurements in that region. It cannot be, therefore, regarded as due to experimental errors.

The *impressed* magnetic field (treating the primary solenoids as infinitely long) was 4·8 C.-G.-S. units. The actual field within the specimen of magnetite (when cold) was of the order 3·4 C.-G.-S. units. The determination of the absolute values of the permeability for the various temperatures is not yet completed. When this has been done we hope to publish (probably in the *Proc.* Roy. Soc.) a fuller account of the methods and result of the investigation.

The Telephone in France.—The balance-sheet of the French telephones for 1891 shows gross receipts amounting to £223,000, the length of line at the end of that year being nearly 1,200 miles, and the number of subscribers 18,191, to which total Paris contributes no less than 9,965.

THE UNITS DISCUSSION AT THE BRITISH ASSOCIATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to my opening remarks at the above discussion, as published in proof in your issue of August 5th, p. 371, I wish to say that, after conversation and correspondence, I did not bring forward all the suggestions there set down, but withdrew Nos. 4, 5, 6, and 8. That is to say, I abandon the idea of altering either the watt or the coulomb, although they are rather small for practical purposes. I am further disposed to amend No. 12 by recommending for the "gauss" $0{\cdot}4\,\pi$ ampere turns, instead of one ampere turn.

The resolutions that I wish to press are Nos. 1, 9, 10, 11, 14. It is influentially felt that the nomenclature of magnetic units had better be deferred for a time; but, meanwhile, teaching is much more difficult than it would be with a couple of judiciously chosen names for quantities in the magnetic circuit.

There is a slip in the proof you printed, which I will ask you to correct, viz., in the ninth paragraph, under head "total induction," I say there that the pull between two parallel surfaces [one square centimetre in area] joined by a weber is so much. The words in square brackets were omitted by me, thus making an error. The pull depends not only on the total lines, but on their concentration; a weber distributed over a square metre of area would give a pull of only 40 tons.

I have received letters from Dr. Fleming, Prof. A. Gray, and Mr. James Swinburne, and these I send as valuable contributions to the discussion, if you obtain the authors' consent to their appearance.—Yours, &c.,

OLIVER J. LODGE.

With many of Dr. Lodge's suggestions I entirely agree, especially in the desire to give simple names to the practically used units. First, amongst the practical units not already named, but for which a name should be fixed, is the practical unit of magnetic induction. As a short practical name for a total induction of 10^8 magnetic "lines," I have generally used the term "gauss;" and in a Note in *The Electrician* for 1890, Vol. XXV., p. 445, suggested the word "Gilb" or "Gilbert" for the same as an alternative. Whether we adopt "Gauss," "Gilbert," or "Weber" as the name of this unit of total induction there are many good reasons for taking the practical unit as equal to 10^8 C.-G.-S. units, although most inductions which occur in practice would only be fractions of this practical unit in magnitude. With respect to the unit of magneto-motive force it hardly seems necessary to christen the ampere-turn. On the other hand, *80 ampere-turns* is very nearly = 100 C.-G.-S. units of magneto-motive force, and might very conveniently be named.

There ought to be a simple relation between the so-chosen units of total induction and magneto-motive force when considered with reference to a non-ferric circuit. As the term "gauss" has been used for a unit of total induction, I should prefer to see it kept to denote 10^8 "lines of force," and the term "weber" applied to the unit of magneto-motive force, whether 80 ampere turns or to 0·8 ampere-turn $= \frac{10}{4\pi}$ ampere-turn.

With respect to other proposed changes, the suggestion to call a micro-farad a farad will probably meet with acceptance; but it is questionable whether the proposal to make the "watt" a unit of energy instead of power will be so favourably received. The watt is a convenient unit for measuring the power given to an incandescence lamp or taken up in a transformer, and the power sent out from an electric station is equally well measured in kilowatts or megawatts. The Board of Trade unit of energy, which has not yet been successfully named, might quite well be left as it is at present, and simply called "a unit." The non-electrical public would not understand its meaning a bit better by giving it a name, and the electrician thinks of it as a kilowatt-hour analogously to ampere-hour. I hope it may be possible to arrive at a decision on the subject of a practical name for the unit of inductance or coefficient of self-induction. There seems much to be said in favour of adopting the term "Henry," and it has, in fact, been widely used for the name of that unit, which is variously called a secohm or a quadrant.

Substantially, then, I agree with Dr. Lodge's proposals, only I would prefer to see the "gauss" taken as the unit of total induction and the "weber" as the unit of magnetic potential, and made equal to 80 ampere-turns, or to $\frac{1000}{4\pi}$ ampere turns, to facilitate calculations. This will make the unit of magnetic potential equal to the difference of magnetic potential between two points ten centimetres apart in a uniform magnetic field, whose strength is 10 C.-G.-S. units. I deprecate, however, the change of the "watt" into a unit of energy; the "watt" and "kilowatt" should remain units of power.

J. A. FLEMING.

I agree with Dr. Lodge on the whole, and should like to see some of the reforms he advocates introduced. There are a few points, however, on which I rather differ from him; but perhaps we do not differ very much, after all. It is not, I think, a matter of no moment what we call a unit, and names of eminent electricians, if used for this purpose, should not be mutilated or distorted more than can be helped. I dislike, for example, the word *mho* or *mo* on this account very much. It is a *perversion* which I am sorry Lord Kelvin gave his authority to. It is also much to be regretted that Mr. Oliver Heaviside, who has done so much for the improvement of electrical nomenclature, should talk of such things as *Macs*! *Mac* has nothing to do with the name Maxwell whatever, and even if it had it would be quite as great a barbarism as *Am*, which has come into use. Life is surely not so short that we have to contract mere great names into what are dangerously like grotesque and familiar nicknames, which one hardly cares to associate with the great men whose memory it is designed to perpetuate by association with electric and magnetic units. If it is, another reason has been added for thinking life not worth living. If we must have monosyllables, and cannot get them without cutting up or perverting names of illustrious electricians, let us endeavour to find if possible combinations of vowels and consonants, without any previous associations whatever.

A. GRAY.

[ABSTRACT.]

As electrical units are a subject in which I take interest, I will offer some remarks.

Although in dealing with the charge of station batteries the coulomb is useless, it is convenient in dealing with circuits with pilot coils and ballistic galvanometers. Hibbert's magnet standard of what Dr. Lodge would call turn-weberage, or micro-weberage turns, is conveniently given in ohm coulombs. Then, with a given galvanometer resistance, we know the time integral of the current at once. If the electrostatic units are to have names they should not be names of people, but should be in same system as dyne, erg, &c.

The farad is, of course, too large. It does not take long to say micro-farad, and people know what it means. They will not if a change is made.

The name watt is universally used and universally understood, and it is quite useless to change it. The watt is never used by engineers to denote energy. The Board of Trade call 3,600 joules a supply unit. This barbarous term will cause less trouble than calling it a watt.

A name is wanted for total induction. I always use either "total induction," or "field." What Dr. Lodge calls a weber 10^8 "lines" has been called a "gauss," and I think also a "thom" or "tom," and a "hop." As it is a practical unit it might have a man's name. It should be 10^8 lines, not $\cdot 4\,\pi\,10^8$, as that would be very inconvenient.

If we are going to have magnetic reluctance ideas we do not need self-induction. Self-induction is a purely academic notion. In practice one always has to deal with a back or forward E.M.F. The definition of self-induction as the field per ampere multiplied by the turns is fundamentally wrong for practical purposes, it should deal with $d\,\mathrm{F}/d\,c$ not C. All practical magnetic circuits have iron and variable coefficients of self-induction. Similarly the electrokinetic momentum can only come in as a rate of increase or decrease, and $d\,\mathrm{F}/d\,c$ and $-d\,\mathrm{F}/d\,c$ are seldom numerically equal. Self-induction is an absurd idea anyhow for practical work. $\mathrm{L} = \cdot 4\mathrm{T}^2\mathrm{K}$ where K is the conductivity or magnetic willingness or whatever Mr. Oliver Heaviside calls it. K varies with the excitation, of course. Generally the term "magnetic circuit" is meaningless, for it is not defined. In this equation, however, the K really includes the field through each turn. In fact $\mathrm{L} = \Sigma\, t\mathrm{K}$. It is the vagueness about the circuit that makes the magnetic resistance idea so little use. The magnetic resistance of a "tube" of magnetic field is something definite. The magnetic resistance of a dynamo circuit is indefinite on account of leakage cutting the exciting coils themselves.

Magneto-motive force is a wrong term. A force is the slope of a potential, not a potential. Maxwell mixes electric force $\frac{d\,v}{d\,l}$, or $\nabla\,\mathrm{V}$. I think he writes it independently of x y and z, and electromotive force V or $\mathrm{V}_1 - \mathrm{V}_2$. I always call the ampere turns "excitation;" there is no need to call it magneto-motive force. As to suppressing $4\,\pi$, it must come in somewhere else, so it may as well be left where it is.

Before making new units those in currency should be employed correctly. For instance, specific resistance should be in ohm-centimetres, not in ohms. Hospitalier uses this term, and I am the only Englishman, as far as I know, who follows him. I think I am alone, or nearly alone, in writing of megohm-miles, and not of megohms per mile. Again, most writers, even the most scientific, write of quantity of current or strength of current, when they mean current. It is as bad as "rate of speed." Again, "passing a current" is absurd. Passing electricity is correct, and the current is the rate at which it passes. Some day the system of nomenclature may be simplified by the popularisation of the idea of the curl. Anything which gives simple relationships avoids extra names. About two years ago a German writer brought out a treatise on dynamos, in which he regarded induction as a sort of spiral arrangement, a bundle of infinitesimal corkscrews of infinitesimal pitch. He had really got hold of the notion of curl relationship between the electric and magnetic circuit, and worked it out independently. Any simple relationship avoids useless names. Volt-ampere was really much better than watt, and volt-coulomb than joule.

The electric circuit is a particular case of a solenoidal distribution; the magnetic circuit is another, and there are some dozen more. Except that they are both particular but different cases, they have nothing in common. The magnetic circuit corresponds to the displacement circuit in electrostatics. B corresponds with electrostatic induction, electric with magnetic force, and so on. To compare B with current density is absurd, and can not help even the practical man. By all means let it be understood that there is such a thing as a magnetic circuit, but not that it is analogous in particular to the electric circuit. At Cardiff I mentioned that L was no

Digitized by Google

use in practice, and that no one at my works knew what the coefficient of induction of a transformer was, and I was told that this was a disgraceful state of ignorance.

I do not know if I am in order in suggesting that standard cells should not have a so-called saturated solution of $ZnSO_4$. It is not definite. A "normal" solution would be definite, and is easily made up. It gives a lower temperature coefficient, and if real mercurous sulphate is used instead of a mixture of sulphates it would be found that they were more accurate than standard resistances. Even if saturated cells agree it does not follow they are right, as their temperature coefficients vary together.

JAMES SWINBURNE.

THE VARLEY TESTIMONIAL.

The following letter has been extensively circulated amongst the members of the electrical profession :—

For a considerable time past there has existed a feeling amongst some of the older members of the electrical profession that the life-long labours in electrical research of Mr. S. A. Varley should be recognised by some substantial testimonial befitting his reputation as a scientific investigator. It was suggested some time ago by several technical journals that the electrical trades would be doing a gracious and just action by presenting Mr. Varley with some substantial token of their indebtedness ; but the suggestion did not assume any practical shape until recently, when the following gentlemen manifested their willingness to co-operate, and expressed their hearty sympathy with the object in view :—Major Flood Page, Mr. Augustus Stroh, Mr. F. L. Rawson, Sir David Salomons, Mr. Thos. Parker, Dr. John Hopkinson, Mr. Alexander Siemens, Mr. D. de Castro, Prof. D. E. Hughes, Mr. W. A. Gorman, Mr. J. W. Swan, and Mr. R. E. Crompton.

A meeting was held on Friday, June 17th, in the rooms of the Institution of Electrical Engineers, at which were present Messrs. R. E. Crompton, T. E. Gatehouse, W. A. Gorman, Prof. D. E. Hughes, T. Parker, Major Flood Page, A. Stroh, and J. W. Swan, when a resolution to the following effect was passed and sent to the technical press for publication :—"That this meeting was unanimously of opinion that Mr. Varley deserved substantial recognition, and that everyone interested in electrical engineering should be invited to join the committee for the purpose of discussing the best form that this recognition should take, and that a draft circular should be prepared ready for submission to a meeting of a committee, which should be invited to attend at the rooms of the Institution of Electrical Engineers, at 28, Victoria-street, S.W., on Friday, July 1st, at 4 o'clock."

This meeting was accordingly held, and a considerable number of gentlemen were present, including Lord Kelvin, Major Flood Page, Mr. A. Siemens, Profs. D. E. Hughes, John Perry, Silvanus P. Thompson, and George Forbes, Messrs. T. E. Gatehouse, R. E. Crompton, A. Stroh, W. Gorman, and others. Lord Kelvin took the chair. A number of letters were read from gentlemen who were unable to attend, but who had signified their hearty assent with the objects of the meeting. Among these were Sir F. Bramwell, Sir H. Mance, Sir Leppoc Cappel, Sir D. Galton, Sir J. Pender, Dr. Gladstone, Mr. W. H. Preece, Profs. Ayrton, Kennedy, Lodge, and Fitzgerald, Messrs. J. W. Swan, Belshaw, J. E. H. Gordon, Manville, Massey, R. K. Gray, Jackson, and Goolden. Mr. T. E. Gatehouse then gave a very interesting account of Mr. Varley's life, and the services that he had rendered to electrical engineering. After some remarks by Mr. Crompton, Major Flood Page, Mr. Siemens, and Profs. Thompson and Perry, the following resolution was put and carried :—"That this meeting approves of a testimonial being got up on behalf of Mr. S. Varley; that the whole of these gentlemen who have given their names as willing to serve on the committee be, and are hereby appointed a committee to act in the question of the Varley Testimonial, and that an executive committee be hereby appointed, consisting of Lord Kelvin, Prof. S. P. Thompson, Prof. Perry, Mr. A. Siemens, and the gentlemen who attended the preliminary meeting." Among other matters it was suggested that the aid of the Institution of Electrical Engineers be sought to ask that the Government should grant a pension to Mr. S. A. Varley; and that the general committee should consist of the gentlemen who had attended the preliminary meeting, those who had attended that day, and all the gentlemen who had written expressing their sympathy with the objects of the meeting, and that every effort should be made to extend the list. Further, that a statement setting forth what Mr. Varley has done should be prepared by Messrs. A. Siemens, T. E. Gatehouse, Silvanus P. Thompson, and R. E. Crompton, and that this statement, which follows, should be circulated as widely as possible among members of the electrical profession at home and abroad. A brief sketch of Mr. Varley's career will serve to show what signal services he has rendered to the cause of electrical science and the honour his discoveries have conferred upon this country.

Mr. Samuel Alfred Varley was born in London in 1832, and was the third son of the late Mr. Cornelius Varley, an active scientist and artist, and one of the founders of the old Water Colour Society, now the Royal Institute. At the age of 14 Mr. Varley commenced to study chemistry, and attended every scientific lecture he could obtain access to. In 1849, in conjunction with his elder brothers, he made numerous experiments, constructing with his own hands some hundreds of battery cells, but the troublesome manipulation attendant on their use caused him to turn his attention to magnetism. In 1852 Mr. Varley entered the service of the Electric Telegraph Company, and assisted in some experiments on the retardation of electric signals through underground and submarine circuits, which led to the development of his elder brother's (C. F. Varley) double-current system. In 1854 Mr. Varley was appointed to the charge of the telegraphs of the Liverpool district. About this period he constructed an electric chronograph, to measure the small intervals of time occupied by the passage of the electric signal to time balls and the time lost in the discharging apparatus. In the spring of 1855 Mr. Varley was appointed to the charge of the first field telegraphs used in war, and proceeded to the Crimea. After the fall of Sebastopol he took charge of the submarine telegraph connecting Constantinople and Varna. In 1858, when the Atlantic Cable was being constructed, he wrote a Paper, read before the Institution of Civil Engineers, "On the Electrical Qualifications requisite in Long Submarine Cables," and was shortly afterwards elected an associate member of that Institution. In the Paper referred to above, Mr. Varley opposed the views of the electrical advisers of the Company. Faraday, who had publicly supported their opinions, endorsed Mr. Varley's ideas immediately after receiving a copy of his Paper. Mr. Varley followed this up by reading a second one before the Society of Arts in 1859, "On the Practical Bearing of the Theory of Electricity to long Submarine Telegraphy." In this Paper he suggested, among other things, the use of artificial lines, which have since proved of such value in connection with duplex working. In 1866 Mr. Varley discovered for himself the reaction or self-exciting principle, and at that early date constructed his first machine of the pure dynamo type which is now in the Museum at South Kensington. His dynamo of 1866 was exhibited at the Inventions Exhibition of 1885, and for this he was awarded a gold medal. The controversy which subsequently arose on this invention may be held to have been fitly summed up by the late Robert Sabine, C.E. (son-in-law of Sir Chas. Wheatstone), in the following words :—"Prof. Wheatstone says he was the first to complete and try the reaction machine. Mr. S. A. Varley was the first to put the machine officially on record in a provisional specification, dated December 24, 1866, which was, therefore, not published until July, 1867. Dr. Werner Siemens was the first to call public attention to the machine in a Paper read before the Berlin Academy on January 17, 1867." (See *Engineering*, November, 1877.) In 1866 he introduced needle-telegraph coils, in which soft iron magnetically-induced needles were substituted for tempered steel needles. These induced and consequently undemagnetisable needles entirely superseded the old form introduced by Wheatstone and Cooke, and were largely adopted by the Postal Department. In the same year (1866) he designed a system of electric train inter-communication. In the year 1875 Mr. Varley became assistant-manager of the works of the late British Telegraph Manufactory (Limited); and as the first Gramme machines constructed in England were manufactured by this firm, he had ample opportunities of studying the characteristics of both series-wound machines and those having a separate armature for excitation of the field magnets. There is scarcely a doubt that Mr. Varley's investigations at this period led to the invention of compound winding; for in 1876 he patented a series-shunt or compound-wound dynamo, and, in three legal suits, the claim that this specification first described a system of compound winding has been fully sustained. Mr. Varley has from time to time contributed Papers read at the meetings of the British Association, among which may be mentioned one "On the Mode of Action of Lightning on Telegraph Circuits," wherein he described a lightning bridge designed by himself, a number of which are now doing duty, although fitted up more than 20 years ago.

But Mr. Varley's *magnum opus* is the important part which he took in the invention and perfecting of the dynamo, perhaps the most striking invention of the century, and upon this his fame as a patient, conscientious, and earnest scientific investigator of the Faraday school will permanently rest. His researches were undertaken in the true spirit of science, and no thought of self-emolument has ever caused him to deviate from the path which he has pursued throughout an eventful, although eminently simple and blameless life, a life in which self-denial and self-sacrifice have had no small share. Like many men of genius he was far ahead of the times, and has lived to see others reap the benefit of his great discoveries. His nervous and retiring disposition has for years kept him from the busy haunts of men, and to the younger generation of electricians he exists only in name—a name, however, that will live as long as the dynamo is employed in the service of man.

The Committee consists of Lord Kelvin, Sir Leppoc Cappel, Sir Frederick Bramwell, Sir Henry Mance, Sir John Pender, Sir Douglas Galton, Sir David Salomons, Prof. Ayrton, T. O. Belshaw, G. Binswanger, R. E. Crompton (Hon. Sec.), D. de Castro, D. Fitzgerald, Prof. George Forbes, T. E. Gatehouse, Dr. Gladstone, W. T. Goolden, J. E. H. Gordon, W. A. Gorman, R. K. Grey, Prof. D. E. Hughes, Dr. John Hopkinson, R. C. Jackson, Prof. Kennedy, Prof. Oliver Lodge, E. Manville, W. H. Massey, H. Mavor, Major S. Flood Page, T. E. Parker, Prof. Perry, W. H. Preece, F. L. Rawson, A. Siemens, A. Slatter, A. Stroh (Hon. Treasurer), J. W. Swan, Prof. S. P. Thompson. Subscriptions may be sent to the Hon. Treasurer, at 98, Haverstock-hill, N.W.

British Association Money Grants.—At the meeting of the General Committee of the British Association last Wednesday week the following were among the grants made for scientific purposes :—Prof. Carey Foster, electrical standards, £25, and Mr. H. Fox, magnetic work at the Falmouth Observatory, £25. The total sum granted was £1,000. The committee subsequently adjourned to meet again at Nottingham on September 13, 1893.

THE BOARD OF TRADE AND ELECTRICITY METERS.

The following letter to the London County Council relating to the approval of electricity meters by the Board of Trade, has been sent us for publication :—

(Copy.)

Board of Trade (Railway Department),
London, S.W., August 15, 1892.

Electric Lighting Acts, 1882 and 1888.

Sir: With reference to previous correspondence on the subject of the approval by this Department of the pattern and construction of electricity meters for the purposes of Electric Lighting Orders, I am directed by the Board of Trade to inform you that, having carefully considered the several patterns of meters which have been submitted for their approval, they are of opinion that it is desirable that they should have further experience of the practical working of the meters in actual use before any formal approval is given. Though some of the patterns of meters which have been submitted have many merits, and the laboratory tests which have been applied have been, in several particulars, satisfactory, no meter has shown such perfection in principle, design, and construction, as to justify the Board of Trade in the conclusion that serious defects might not appear in actual working. Under these circumstances the Board of Trade are of opinion that further experience of the behaviour of meters should be gained, and possibly further inquiry made, before the final decision of the department is arrived at. Representations, moreover, have been made to them with regard to the effect on the interests both of those who are engaged in supplying electrical energy and of those whose efforts are being continuously directed to the invention of meters which would be produced were any approval, even of a temporary and provisional kind, to be given now to any particular pattern or patterns of meter.

With the view of acquiring as fully and as thoroughly as possible information as to the behaviour of meters under working conditions, the Board of Trade would be glad of the co-operation of the London County Council in providing for a thorough practical test ; and they would suggest that the Council should, at their early convenience, instruct their representative to confer with Major Cardew, the electrical adviser of the Department.

Pending the acquisition of this information, which they anticipate will occupy a period of about twelve months, the Board of Trade are not prepared either to approve the pattern and construction of any electricity meter not yet approved, or to further extend the approval already given in the case of the Shallenberger meter, which has been approved for the purposes of the following Act and Orders only, namely :—The Metropolitan Electric Lighting Act, 1889 ; the Metropolitan Electric Supply Company (West London) Lighting Order, 1889 ; the Metropolitan Electric Supply Company (Mid-London) Lighting Order, 1889 ; the Metropolitan Electric Supply Company (Paddington) Lighting Order, 1890 ; the House to House Electric Light Supply Order, 1889.—I am, &c.,

(Signed) Courtenay Boyle.

The Clerk to the London County Council,
Spring Gardens, S.W.

SOURCES OF HEAT GENERATED IN THE GALVANIC BATTERY.*

BY MAGNUS MACLEAN, M.A., F.R.S.E.

These experiments were suggested by a Paper read by Lord Kelvin to the British Association in Belfast in 1852, and reprinted in "Mathematical and Physical Papers," Art. LV. In that article it is stated "that a feeble continued current, passing out of an electrolytic cell by a zinc electrode, must generate exactly as much more heat at the zinc surface than the same amount of current would develop in passing out of an electrolytic cell by a platinum electrode, as a zinc platinum pair working against great external resistance would develop in the resistance wire by the same amount of current."

In the first set of experiments two equal and similar glass vessels were used, with about 500 c.c. of dilute sulphuric acid in each. The pairs of elements were Zn Zn, Zn Pt. The rise of temperature due to currents of from 4 to 14 milliamperes, obtained from the Smee cell, was observed at intervals of a few minutes for about four hours. There are many sources of error in this mode of experimenting, besides the difficulty of observing the small rise of temperature ; but generally the rise of temperature of the Zn Zn cell was greater than that in the Smee cell. In some of the experiments the Smee cell showed a higher rise of temperature ; but this latter result is no doubt due to local causes, such as polarisation, &c.

In the second set of experiments a current of 39 milliamperes was obtained from the Smee cell, and in every case the rise of temperature of the Zn Zn cell was greater than the rise of temperature of the Smee cell ; and the average rise corroborates the statement of Lord Kelvin quoted above.

Thus average rise of temperature of Zn Zn cell above Smee cell is 0·2° C., and hence heat generated = 500 × ·85 × 0·2 = 85. Equating this to the work done by Smee cell in four hours, we get

$$E = \frac{85 \times 42 \times 10^7}{\cdot 0039 \times 4 \times 3{,}600} = \cdot 64 \times 10^8 = \cdot 64 \text{ volt.}$$

In the third set of experiments the two elements in each cell were separated by a piece of blotting-paper, and four thermometers used to indicate the rise of temperature at each electrode. It was found that the rise of temperature at the zinc anode plate was greater than at the zinc cathode.

In another series of experiments with four cells containing dilute sulphuric acid, in which the pairs of elements were Zn Zn, Pt Pt, Pt Zn, and Zn Pt, currents from an external source of half, one, and two amperes were allowed to flow for about an hour, and the rise of temperature in each cell recorded. Tables of results are given showing that the rise of temperature in the cell in which the current flowed from platinum to zinc is in every case higher than the rise of temperature in the cell in which the current flows from zinc to platinum. Taking the average of a number of experiments fairly agreeing among themselves, it is found that the mean rise of temperature in the four cells is :—

Time experiments lasted.	Current in amperes.	Zn Zn.	Pt Pt.	Pt Zn.	Zn Pt.
1 hour	½	0·45	0·6	0·53	1·07
40 minutes	1	0·45	0·75	0·6	1·37
1 hour	2	2·8	3·98	2·53	4·98

Direction of current <———

Mr. George E. Allan, Thomson Scholar in the Physical Laboratory of the University of Glasgow, carried out the larger number of the later experiments.

SOME EXPERIMENTS WITH A RUHMKORFF COIL.*

BY MAGNUS MACLEAN, M.A., F.R.S.E., AND ALEX. GALT, B.SC., F.R.S.E.

The quantity of electricity induced in a secondary circuit by a *make* in a primary circuit is equal to the quantity of electricity induced in the same secondary by a *break* in the primary. This fact was first experimentally proved by Faraday, and subsequent experiments and theory corroborate the statement. If, however, there is a non-metallic gap in the circuit, whether of air at ordinary pressure, or at much reduced pressure, as in vacuum tubes, the *break* impulse causes a flow in one direction, and the *make* causes either no flow or a much less flow in the opposite direction ; because the short intense impulse of the former breaks down the resistance, while the comparatively long and less intense impulse of the make either does not break down the resistance at all, or only does so to a much less degree, so that the effective resistance is much greater in one direction than in the other. To obtain the average difference of quantity of electricity set in motion in one direction above that in the other, a copper electrolytic cell was put in circuit with a vacuum tube and the secondary coil of a small Ruhmkorff coil. The solution in the cell was sulphate of copper of density 1·17 with one-half per cent. of commercial sulphuric acid added. The electrodes were No. 36 B.W.G. copper wire 0·012 centimetre diameter, and they were immersed in the solution as little as possible, so as to get the best current density for the deposit. The mean of seven experiments lasting from two to four hours gives the average electrolytic current, calculated from the gain of the cathode electrode, as one sixth of a milliampere. The gain of the cathode electrode was, in six of the seven experiments, greater than the loss of the anode electrode. An electrolytic cell was also put into the primary, and the mean ratio, in three experiments, between the gain of the cathode in the primary and the gain of the cathode in the secondary was 6,000. The mean current in the secondary was still about one-sixth of a milliampere.

One or two experiments were also tried without a vacuum tube in the secondary circuit, simply the electrolytic cell. Both electrodes showed loss. Again, a long thermometer tube full of sulphate of copper solution was substituted for the vacuum tube. The resistance of this tube would be comparable to that of the vacuum tube. (A Thomson multicellular was put at the terminals of the vacuum tube, which showed 165 volts. This would give the effective resistance of the vacuum tube to disruptive discharges as $165 \div \frac{1}{6000}$ = one megohm.)

The few experiments done with this thermometer tube in the circuit are inconclusive, as sometimes both electrodes showed loss,

* Paper read before the British Association, in Section A, Edinburgh, August, 1892.

* Paper read before the British Association in Section A, Edinburgh, August, 1892.

Digitized by Google

and in an experiment lasting hours neither electrodes showed either gain or loss. These last experiments are to be continued with slight modifications. It is also intended to attach a tube to an exhaust pump, and try these electrolytic experiments at different pressures, from atmospheric pressure down to very low pressures or very high vacuums.

THE HUMAN BODY AS A CONDUCTOR OF ELECTRICITY.*

BY H. NEWMAN LAWRENCE, M.I.E.E.

That the human body is no ordinary conductor has been long acknowledged, but the peculiarity of its conductivity and the conditions under which this conductivity varies are subjects which have hardly yet been satisfactorily investigated. Much has been done to determine the true resistance of the living body, and a near approach to the solution of the problem has been arrived at, but the difficulty of the relative value of the resistance of skin and the internal portions of the body still remains. This difficulty is all the greater because, as has been shown by Erb, the skin on different parts of the body differs in its conducting power even after contact area and surface soakage have done all that is possible for them in the way of equalising matters. A knowledge of the distribution of conductivity, and how each particular section acts to the passage of current after the initial resistance has been overcome, is of scarcely less importance in connection with accidental contacts than that of initial resistance itself.

In a former communication which the author made to the Association (in conjunction with Dr. Harries) he dealt at some length with the resistance of the body to different forms of current. Since then he has made other observations, and though these are still incomplete, he has embodied some of them in this Paper in the hope that friendly criticism may help to a satisfactory solution of the problem at no distant date.

The author has endeavoured to separate from the total resistance of the body that portion which belongs to the skin alone. Carpenter, Stone, Stein, and quite recently Hedley, have adopted various methods to arrive at the same end, but their results can hardly be considered conclusive. By the use of internal as well as external electrodes he is led to conclude that the resistance of the skin of the cheek, or of similar skin, when circular non-polarisable electrodes of 2in. diameter are used, is 934 ohms for one layer, or 1,868 ohms for the two layers, as in ordinary contacts. These figures are, however, by no means true for skin in all parts of the body, because the number of sweat and other glands differs in many parts, and the extent of their presence in a given area has much influence upon the resistance and consequent conductivity of that area.

A number of readings obtained by passing continuous current for five consecutive minutes through different parts of the body appear in tables accompanying the Paper, and serve mainly to show the great power a steady flow of current, even for a short time and at low electromotive force, has to increase the conductivity of nearly all parts of the body. Some of the results are plotted on squared paper for more easy comparison. They form an interesting study, and, though manifestly incomplete, throw some light upon the distribution of conductivity throughout the limbs and trunk. That these figures would be very different when currents at the comparatively high electromotive force of light and power circuits were passed is almost certain, but there does not seem much reason to suppose that the distribution of conductivity would thereby be altered. It is to be noted that this Paper deals with the effects of continuous current only. Those of alternating currents require separate investigation.

ELECTROLYTIC SYNTHESIS OF DIBASIC ACIDS.†

BY PROF. CRUM BROWN AND DR. JAMES WALKER.

When potassium ethyl malonate is electrolysed in strong aqueous solution there occurs at the positive electrode, besides actions resulting in the evolution of oxygen, the following synthetic reaction :—

$$2EtOOC.CH_2.COO. = EtOOC.CH_2.CH_2.COOEt + 2CO_2.$$

Thus from malonic acid there is obtained succinic acid, the next member in the series of saturated dibasic acids. In the same way there may be obtained from succinic acid adipic acid ; from adipic, sebacic ; from glutaric suberic ; and from suberic and sebacic acids two new acids of the formulæ $HOOC.(CH_2)_{12}.COOH$ and $HOOC.(CH_2)_{16}.COOH$. Acids with side chains behave in a similar manner, thus from methyl malonic acid there are obtained the two inactive symmetrical dimethylsuccinic acids. Amongst the other products of the electrolysis there are found ethyl ethers of unsaturated acids, for instance, acrylic ether in the case of the electrolysis of pthyl potassium succinate. The formation of this substance may be represented by the following equation :—

$$EtOOC.CH_2.CH_2.COO. \quad EtOOC.CH_2.CH_2.COOH$$
$$+EtOOC.CH_2.CH_2.COO. = +EtOOC.CH_2.CH_2 + CO_2.$$

The positive pole employed was a spiral of platinum wire, and the negative pole a platinum crucible of about 40 cc. capacity. The E.M.F. was 12 volts, the current being about 4—5 amperes.

* Abstract of a Paper read before the British Association in Section D, Edinburgh, August, 1892.

LEGAL INTELLIGENCE.

Clegg and Sons v. The International Okonite Company (Limited).

This action was brought by the plaintiffs, who are architects in Manchester, against the defendants, manufacturers of electrical wires and cables at Newton Heath, for professional services in connection with the erection of defendants' works. The defendants counter-claimed damages for alleged negligence. The case was heard last week at the Liverpool Assizes, before Mr. Justice Denman, who delivered judgment on Monday. His lordship said the claim was for £129. 13s. 3d., balance of commission earned and work done by the plaintiffs, and the question was, had the plaintiffs made out that they were entitled to remuneration at the rate of 3 per cent. commission, which was claimed, or at the rate of 2½ per cent. He thought that they had made out that part of their case, subject to any small deduction with regard to the amount on which the commission was to be claimed. The second item in the claim was for £73. 6s., which was for a good many things, such as preparing drawings, original surveys, &c., and he did not think this claim was other than a fair and reasonable one. With respect to the counter-claim, he did not find that the defendants had suffered any damage by reason of any negligence on the part of the plaintiffs. His lordship therefore gave judgment for the plaintiffs for the amount claimed on the claim and counter-claim, with costs.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *August* 6, 1892.

The Electrical Engineering Department of Cornell University.—The annual report of President Adams, of Cornell University, indicates that the electrical engineering department of that Institution is in a thriving condition. Since this department was organised about ten years ago by Prof. W. A. Anthony, the number of students registering each year has been constantly increasing, until in 1891 and 1892 the total number taking the studies in the electrical engineering department was 250. From 1884 to 1891 the number of students registered was 28, 40, 59, 83, 125, 172, 214, and 250. The graduates of the same department for the period 1886-1892 were 5, 7, 8, 19, 28, 28 and 46 for the respective years. During the past few years the department of physics under the charge of Prof. E. L. Nichols has carried on a great deal of original work, the results of which have been published in twenty-five different periodicals in the English, French, German and Italian languages. These Papers have been written by over thirty different authors, including professors, instructors and students.

An Automatic Telephone Exchange.—A rather ingenious apparatus for displacing operators in a central telephone exchange has been brought out by the Strowger Automatic Telephone Company of this city. This company is exhibiting at its rooms a model installation for the purpose of showing the method of working the system. The operation and the apparatus used are not at all complicated, and seem to perform the work for which it is designed with very little chance of failure. The apparatus is intended to enable any telephone subscriber to connect his instrument with that of another subscriber whose number he knows. Five keys are provided for each subscriber, namely, one key numbered units, another tens, a third hundreds, and a fourth thousands, while the fifth key is used to release the connection after conversation is finished. In case a number, say 131, is desired, the subscriber

Digitized by Google

presses the unit key once, the tens key three times, and the hundreds once. The closing of the circuits in this way by these keys sets into operation a little instrument 4 × 4 × 6in. which each subscriber has in the central exchange in such a way as to connect his line with the line of the subscriber with whom he wishes to converse. No operators are required in the central exchange, and all the attendance necessary is whatever is needed to keep the apparatus in repair.

The Late Mr. Cyrus Field.—The will of Cyrus W. Field, made public this week, discloses the fact that the mementoes of the Atlantic Cable laying were not presented to the Metropolitan Museum of Art in this city, as had already been announced.

CORRESPONDENCE.

THE PHYSIOLOGICAL EFFECTS OF ALTERNATING CURRENTS OF HIGH FREQUENCY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I notice in your issue of July 8th, 1892, in commenting upon my Paper, an abstract of which was published in the *Electrician*, Vol. XXVI., p. 644, on the "Physiological Effects of Alternating Currents of High Frequency," you say, "but not a hint was given about the methods of measuring such currents."

It is but just to Dr. Tatum, who died shortly after writing about his experiments, the results of which were given in his letter to me, and published under the above title, to say that it is my impression he wrote me that in measuring the high frequency currents he used a hot wire ammeter, which he had already used in his experiments of 1890, to which you refer. In his experiments on the physiological effects of high frequency currents he used currents of 4,500 alternations per second, and found that a greater strength of such currents could be more readily borne by a dog than if the current were continuous.

You quote Prof. E. J. Houston as saying that "at extraordinary high frequencies all harmful physiological effects practically disappear." I would remark on this statement that it may be true, but it is not proven. Dr. Tatum's results point to the fact that it is probable, that as the frequency increases, a larger and larger current would be required to produce injury, but it is well known that the discharges of a Leyden battery are of extraordinarily high frequency, but it can hardly be claimed that such an oscillatory discharge continued for a moderate interval of time would be without harmful effect. A considerable size of battery may be discharged through a person without necessarily injuring him, although the shock will be violent. The absence of injury in this case may be, and probably is, due to the fact of the extremely brief duration of the discharge. Permit me to suggest that the superior immunity from harmful effects when high frequency currents are passed through the body may be, at least in part, due to some other influence than mere "skin" effect. May not the fact that the living molecules have some chance of recuperation or restoration during the zero periods or times of practically no current passing, which with high frequency currents are increased in number and are nearer together, account for the effect noticed aside from the peculiarities in the distribution of the currents?

In my correspondence with Dr. Tatum before his death, this resting of the molecules at the zero points was suggested by myself as the probable cause of the comparative immunity found, and there may, of course, be some property akin to sluggishness of effect upon these molecules which would lessen the harm in the case of very high periodicities. If the high period current traversed the body mostly by the surface, or skin, then the sensation ought to be greatly increased over what is found with a lower period, or with continuous currents; but Dr. Tatum found in his experiments that there was very little difference to be detected in the degree of sensation or unpleasantness of the currents of various periods. From the fact that much of the fatty tissues of the body underlies the skin, and that the outer skin is a comparatively poor conductor, it would seem that a considerable portion of any skin effect would be neutralised, and the current, unless the frequency were indeed extraordinarily high, would be distributed over the body in a measure in accordance with the conductivities of the tissues, which in turn would depend largely upon the proportion of dissolved salts contained, and the absence of fat.

It seems to me that we need an extended course of experimentation to be pursued in this field before we are able to say anything as to the causes of the undoubted difference of effect observed between currents of different periods on the animal organism.—Yours, &c.,

ELIHU THOMSON.

Lynn, Mass., July 26, 1892.

CARBON BRUSHES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In a contribution to the recent correspondence in your columns on the subject of carbon brushes, I beg to say that when a low-tension dynamo is fitted with several pairs of copper brushes of ample capacity, good results can be obtained by substituting carbon for one brush on each side, and setting the carbon brushes a trifle in advance of the copper brushes. The copper brushes take care of the current while the carbon suppresses the spark. The adjustment of brushes when starting the dynamo to position of least spark, should be made with copper brushes only: the carbon brushes being dropped on to the commutator after the best position is found.

I adopted this expedient some time ago on a dynamo which had a variable load and attendance of the poorest kind. It was such a success in preserving the commutator that I apply it wherever I have a variable load. For constant-potential dynamos of E.M.F. higher than 220 volts, American practice is to use carbon brushes exclusively. And for motors of 220 volts most manufacturers furnish carbon brushes. These 220-volt motors up to 50-H.P. are very largely used on Edison 3-wire circuits, and almost always with carbon brushes.—Yours, &c.,

D.

Chicago, Ill., August 3, 1892.

THE WESTMINSTER ELECTRIC SUPPLY CORPORATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As many of your readers will have learned of the total extinction of the electric light at the St. Stephen's Club on the evening of the 9th instant, I should feel greatly obliged if you would kindly allow me to contradict in your columns a report which has gained ground, to the effect that the extinction was due to a failure of supply by this corporation.

The misapprehension is due to the fact of the club in question having been lighted for some months, and that without any interruption whatever, by current supplied by this Corporation, until about six weeks ago, when the committee of the club decided to avail themselves of an offer from another source at a cheaper rate, with the result above stated.—Yours, &c.,

EDMUND BAX, Manager.

Victoria Mansions, Victoria Street, S.W.,
August 17, 1892.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

TENDERS INVITED.—The Oldham Corporation require tenders for making and fixing concrete culverts and the laying of electric conductors, and also for the supply of cast-iron pipes and service boxes. Specifications and drawings can in each case be obtained on payment of a guinea (returnable), on application to Prof. Alex. B. W. Kennedy, 19, Little Queen-street, Westminster, S.W., or to Mr. A. Nicholson, Town Clerk, Town Hall, Oldham, to whom tenders must be delivered by September 2nd.

Digitized by Google

TENDERS INVITED.—The Corporation of Derby require tenders for the construction of Lancashire boilers and accessories for their central lighting station. Plans may be seen on application to Messrs. Bramwell and Harris, engineers, 5, Great George-street, Westminster, S.W., or to the Town Clerk, Town Hall, Derby, from whom may be obtained specification and form of tender. Tenders must be delivered to Mr. H. F. Gadsby, Town Clerk, Town Hall, Derby, by 12 noon on 22nd inst.

——— Tenders will be received until March 31, 1893, by the civil authorities of Bougie, Algeria, for the lighting of the town either by electricity or gas.

——— The Municipality of Graz will receive, up to 12 noon on August 31st, tenders for the erection and installation of a central electric light and power station.

TENDERS ACCEPTED.—The Prescot Local Board met on Tuesday to consider revised estimates submitted for lighting the town. The Prescot Gas Company offered to light the public lamps with gas at a total cost of £307. 7s. 8d. per annum; but an offer from the British Insulated Wire Company (Limited) to light the streets by electricity for an annual sum of £350, was unanimously accepted. The Company agree to supply electric light to the existing gas columns (70) with incandescent lights of 12 c.p. during darkness the year round; 10 arc lamps 2,000 c.p., and two arc lamps with 500 c.p., from dusk to midnight; and the Local Board will support the Company in an application to the Board of Trade for a licence under the Electric Lighting Act, 1888, to supply light to private consumers.

——— The Guardians of the Chertsey Union have accepted the tender of Messrs. J. Hamilton and Son, Guildford-street, Chertsey, to construct telephones, electric bells, and speaking-tubes at the Workhouse at Ottershaw for £33.

——— The tender of the Roper Electrical Engineering Company has been accepted for wiring the Bradford Town Hall for electric lighting.

——— The tender of Messrs. Peirson and Co. has been accepted for the supply and erection of the constructional iron work for the Meredith's Wharf Depôt of the City of London Electric Lighting Company (Limited), the amount of the contract being £2,896.

——— Messrs. Lowdon Bros. have secured the contract for installing the electric light to the works of Messrs. A. and J. Macnaughton, Pitlochry.

TENDERS RECEIVED.—At the last meeting of the Walsall Town Council the General Purposes Committee reported that 28 tenders had been received for lighting with electricity a portion of the borough, such tenders ranging from £6,712 to £22,733, and that the Electric Lighting Sub-Committee would visit five or six towns where systems of electric lighting were in operation for the purpose of gaining information.

——— The Electric Lighting Committee of the Yarmouth Town Council have received six tenders for lighting the borough, the lowest of which was between £5,000 and £6,000, and the highest over £23,000.

PREMISES TO LET.—The Westminster Electric Supply Corporation (Limited) advertise elsewhere particulars of some vacant land with workshops erected thereupon, which are to be let, in the S.W. district.

COATBRIDGE.—The Scottish House-to-House Electricity Company (Limited) are about commencing the erection of a central station, and have placed the contract for the machinery in the hands of Messrs. J. E. H. Gordon (Limited).

DUBLIN.—The electric light fittings, the wiring for the electric light, and the telephones (77 in number) in the Hotel Métropole, just opened, were installed by the Electrical Engineering Company of Ireland (Limited), under the superintendence of Mr. Walter Leake.

MR. A. A. C. SWINTON.—This gentleman is installing the electric light at Newbold Revel, the seat of Mr. H. E. Wood. The plant will comprise two Cornish boilers, two Parsons steam turbines and dynamos, a large battery of D.P. accumulators, and some 500 incandescent lamps.

MESSRS. CARRICK AND RITCHIE.—We have received from this firm some illustrated particulars, with price lists, of their well-known Waverley turbines, jet water motors, &c.

TATE'S ELECTRIC VALVE CLOSING APPARATUS.—We are informed that Mr. S. P. Wood, of Hull, has been appointed district agent for this apparatus, by which motive power can be shut off immediately in case of accident.

THAMES ELECTRIC AND STEAM LAUNCH COMPANY.—Mr. Andrew Pears has taken over the Electric and Steam Launch Buildings and Public Charging Station, now in course of construction upon Eel Pie Island, Twickenham, formerly the property of Mr. W. S. Sargeant, of Strand-on-the-Green, Chiswick and Twickenham, and the firm in future will be worked as the "Thames Electric and Steam Launch Company." The whole of the buildings, which have been designed and laid out with the intention of carrying on a very extensive launch building works, and to manufacture everything appertaining to water propulsion, both electrical and steam, consist of two large shops two stories high, one for boat building and joinery, and the other for engineering and electrical work: in addition to these there will be a building having 84ft. span for housing launches, &c., and general repairs. In connection with this a slipway is being fitted complete with a single, double and treble geared hauling winch, driven by an electric motor; this will haul up any size vessel that can navigate the Upper Thames.

POOLE AND WHITE (LIMITED).—A petition for the winding-up of this Company has been presented by Messrs. J. G. Rollins and Co., Old Swan Wharf, Upper Thames-street, E.C., and will be heard by Mr. Justice Vaughan Williams on Wednesday next, the 24th inst.

ATELIERS HOSTER DE ST. NICHOLAS (LIMITED).—An order for the compulsory winding-up of this Company was made on the 11th inst.

MR. RANKIN KENNEDY.—The examination of this bankrupt is to take place at Sheriff Spen's Chambers, Glasgow, on Monday next, the 22nd inst., at 11 o'clock a.m.; and a meeting of creditors is to be held at 82, West Regent-street, on the 31st inst., at 12 o'clock.

FRENCH ELECTRICAL COMPANIES IN LIQUIDATION.—The Compagnie Parisienne d'Eclairage par l'Electricité is being voluntarily wound up.—Messrs. Martin, Ducamp and Co., makers of the "Bimetallic" telephone and telegraph wire, with offices in Paris and works at Joinville-le-Pont, is also in liquidation.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

July 12, 1892.

12,888. L. VON ORTH and E. PRESLAUER. London. Improvements in electrical regulating devices for clocks.

July 14, 1892.

12,906. W. M. HADDOW and J. S. HUTCHISON. Glasgow. Improvements in and relating to "roses" or electrical connections for the ceilings of buildings or structures.

July 15, 1892.

12,977. C. A. BURGHARDT. Manchester. Improvements in the electrolytic production of caustic soda or caustic potash.

12,999. G. KAPP. Manchester. Improvements in the method of and means for distributing electric currents.

July 16, 1892.

13,072. D. RYLANDS and S. SLATER. Barnsley. Improvements in coupling and fixing glass tubes for containing electric wires.

13,090. W. HEDGES. London. Improvements in portable electric lamps and safety fuses for same.

13,095. F. VON POSCHINGER. London. Improvements relating to the electric heating of pottery, and other furnaces and materials therefor.

July 19, 1892.

13,160. T. ODDY. Rochdale. Increasing the efficiency of telephonic communication and transmitting speech.

13,167. W. E. IRISH. London. Electric arc lamp.

13,207. L. STIRN. London. Improvements in incandescent electric lamps.

13,221. W. DECKERT. London. Improvements in or connected with telephones.

July 20, 1892.

13,297. W. W. HORN. London. Improvements in electropathic appliances for human wear. (R. S. Mears and W. C. Powers, United States.)

12,288. H. HIRST. London. Improvements in connections for electroliers and other electric light fittings.

July 21, 1892.

13,323. H. C. BULL and G. B. COWL. Liverpool. Improvements in or connected with the production of electric energy.

13,335. T. WHITTINGHAM. Birmingham. Improved means for signalling by electricity on railways.

13,337. G. W. HANNAM. London. Improvements in electric belts, which improvements are also applicable to other purposes.

13,375. W. L. SPENCE. Manchester. Improvements in or relating to electric meters, recording apparatus, and controlling gear.

13,380. F. B. BEDWELL. London. Improved means of preventing injury to telegraph cables connected with lightships and floating stations.

Digitized by Google

July 22, 1892.

13,381. E. B. Bright and L. W. Mercier. Surrey. Improvements in the manufacture of electrical storage plates, cells, or accumulators, and the accessories thereto.

13,395. M. Mercier. Manchester. Improvements in or relating to electrical apparatus for signalling.

13,405. H. Nehmer. London. Improvements in portable Leclanché batteries.

July 23, 1892.

13,453. G. Bamberg. London. Improvements in electrodes for use in electrolytic apparatus, and in their manufacture.

13,473. G. Binswanger. London. Improvements in apparatus for heating purposes, and cooking by means of electricity.

July 25, 1892.

7,404A. S. H. Short. London. Improvements in or relating to dynamo-electric machines and electric motors. (Date claimed under Patents, Rule 19, April 19, 1892.)

13,507. W. H. Scott. Norwich. Conduits with insulators for underground conductors for the distribution of electricity.

13,541. F. E. Elmore. London. Improvements in the manufacture of continuous lengths of tube by electrolysis.

13,542. F. E. Elmore and A. S. Elmore. London. An improvement in tanks or cells for electrolysis and like purposes.

13,543. Siemens Bros. and Co. (Limited). London. Improvements in electrical installations for producing alternate currents. (Siemens and Halske, Germany.)

13,549. F. V. Andersen. London. Improvements in dynamo-electric machines.

13,557. W. P. Thompson. Liverpool. Improved system of electric traction for railway trains, tramways, and the like, and apparatus in connection therewith. (La Société Anonyme pour le travail electrique de métaux, France.)

13,559. J. Cerpaux. London. An improved telephonic plant for private and domestic use.

July 26, 1892.

13,562. D. Young. London. Improvements in and relating to electrical accumulators for secondary batteries. (A. E. Colgate, United States.)

13,595. J. A. Ewing and C. G. Lamb. Cambridge. Improvements in apparatus for varying the strength and direction of electrical currents.

13,619. W. H. Munns. London. Improvements relating to electrical fire-alarms and the like. (A. H. Brintnell, Canada.)

13,639. A. S. Simpson. London. Improvements in acoustic telephones.

13,648. M. W. Dewey. London. Improvements in electric railways.

July 27, 1892.

13,678. W. R. Webb. London. An electric combination contact bell-push and pull.

13,683. T. R. Andrews and T. Preece. Bradford. Improvements in the method of and apparatus for starting electric motors.

13,694. W. C. Johnson and T. Boyden. London. Improvements in alternate-current transformers.

13,698. F. E. Elmore and A. S. Elmore. London. Improvements in the treatment of mandrels for electrolytic deposit of metallic tubes.

13,702. T. Puskas. London. Organisation and arrangement of a telephonic news transmitter.

13,718. H. L. Doulton and C. E. Morris. London. Improvements in conduits for electric mains and in laying the same.

July 28, 1892.

13,763. J. B. Lee. London. Improvements in incandescent electric lamps.

13,764. J. B. Lee. London. Improvements in the construction of secondary batteries.

13,765. M. Hutin and M. Leblanc. London. Improvements in alternate-current electro-dynamic machines.

July 29, 1892.

13,850. Sir C. S. Forbes, Bart. London. Improvements in incandescent electric lamps and in apparatus connected therewith.

13,854. C. F. Rowley. London. Improvements relating to the application of electricity in connection with chairs, known as "dental chairs," for carrying out dental and other surgical operations.

July 30, 1892.

13,856. G. Binswanger and H. J. Coates. London. Improvements in electric bells.

13,879. E. W. L. Harrison and S. Murray. Manchester. Improvements in telephone receivers.

13,892. R. F. Mann, J. Purvis, and A. R. Burman. London. Improvements in appliances for producing galvanic action for curative purposes.

13,894. W. H. Preece. London. Improvements in submarine telegraph cables.

13,919. E. Thomson. London. Improvement in incandescent electric lamps.

13,920. W. H. Knight and W. B. Potter. London. Improvements in methods of regulating electrically-driven mechanism and apparatus for putting the same into operation.

August 2, 1892.

13,932. J. W. Yates and H. T. Yates. Sheffield. Improvements in telephone switch boards.

13,989. J. W. Gibboney and E. Thomson. London. Improvements in telephones.

13,996. W. Henry. London. Improvements e.ectrical generators.

August 3, 1892.

14,035. J. Pinter. London. An improvemen: n electric incandescent lamps.

14,043. W. J. H. Jones. Liverpool. Improvements in arc lamps.

14,044. J. C. Fell. London. Electrodes for secondary batteries. (W. Morrison, United States.)

14,056. H. H. Lake. London. Improvements relating to electric motors. (W. Stanley, jun., and J. F. Kelly, United States.)

14,060. A. I. Gravier. London. Improvements in dynamo-electric and electro-dynamic machines.

SPECIFICATIONS PUBLISHED.

All Specifications price 8d.

1891.

5,790. Boehm and Bailey. Incandescent electric lamps.

11,108. Coad. Electric batteries.

11,447. Norman and Payne. Electric arc lamps.

11,538. Prokofiew. Conductors for electric propulsion on permanent way.

11,630. Bower. Ribbed metallic plates for secondary batteries.

11,891. Thompson (Dietz). Telephone switch devices.

12,019. Wise (the Rheinische Fabrik für Elektrische Bogenlichtkohle; W. Grüdelbach). Carbons for electric arc lamps.

12,150. May. Magneto-electric time-pieces.

13,362. Forbes. Dynamo-electric machines.

13,384. Forbes. Electrical contacts.

14,040. Lake (Orling). Electric lighting, &c., apparatus for gas burners.

14,097. H. L. and J. Todd. Telephone transmitters.

14,236. Low and Pritchett. Generating and distributing electricity.

14,266. M. and A. E. Humm. Administering electricity to horses.

14,854. Cannot. Insulating electrical conducting wires, &c.

15,050. Le Sœur. Electrolysis.

15,214. Harper. Telephone receiver.

15,243. Wells. Electrical chronographic apparatus.

15,407. Cohen. Galvanic batteries.

15,483. Mewburn (Sée). Electric lighting.

15,579. March. Electric switch and cut-out.

15,697. Graham. Electric telephone transmitters.

15,872. American Elevator Company (Otis Bros. and Co.). Electric motors, &c.

17,426. Andreoli. Generating ozone by electricity.

18,272. Chadwick. Electric belts.

1892.

785. Ries. Incandescent electric lamps, &c.

3,654. Richter. Electric burglar alarms.

4,010. Lockwood. Telephone apparatus.

4,617. Feldkamp and others. Electrical attachments for pianos.

6.007. Parker and Robinson. Cells for electrolysing chloride solutions.

7,509 Lake. (Stanley and another). Alternating-current electro-magnet motors.

9,056. McKay. Electrically giving reciprocating motion.

9,343. Burton. Electric connectors.

9,347. Kellner. Separating alkali from electrolyte.

9,356. Burton. Distributing electric currents.

9,362. Burton. Electric metal working apparatus.

9,365. Lundell and Johnson. Electric motors, &c.

9,379. Burton. Electrically heating and working metal bars.

9,409. Binns. Electromagnets for organs, &c.

9,815. Streeter. Foot supports for telegraph poles, &c,

9,883. Thompson (Coffin). Electric motors.

9,891. McKenna and Weed. Electric meters.

9,947. Hadden (Grammont). Electric conducting wires.

9,983. Thompson (Ries and another). Propelling railway vehicles by electricity.

10,133. Brandas. Electrical insulators.

10,230. Lord Kelvin. Electric condenser.

10,367. Sanche. Connections and terminals for electric wires, &c.

10,715. Jackson. Electrical conductors.

10,762. Weaver and Manypenny. Electric lamps.

10,850. Weymersch. Primary voltaic batteries.

10,870. Lake (Weston). Electrical measuring instruments.

11,032. Harris. Insulating supports for electrical conductors.

11,119. Broadnax. Electric switches.

11,147. Lloyd. Secondary batteries.

11,154. Thompson (Coffin). Welding metals electrically.

11,316. Van Vianen. Electric alarums.

COMPANIES' MEETINGS & REPORTS.

Cuba Submarine Telegraph Company (Limited).

The forty-second ordinary general meeting of the Cuba Submarine Telegraph Company (Limited) was held at the Company's Offices, No. 58, Old Broad street, London, on Wednesday, August 17th, 1892. "to receive the Directors' report and accounts for the half year to 30th June, 1892, to elect a Director and auditor in the room of those who retire, and to transact the other general business of the Company." The chair was occupied by Thomas Greenwood, Esq.

The CHAIRMAN, in opening the proceedings, said: The Secretary will read the notice calling the meeting.

The SECRETARY (Mr. James Scott) having read the notice,

The CHAIRMAN said:—Gentlemen, the Directors have much pleasure in asking your approval of the report and accounts which are submitted to you to-day. They are as favourable, I think, as any which have preceded them, and they cannot fail to meet with your approval. The income has been rather larger than in the corresponding period of the previous year—about £1,100, but this has not arisen from any increase in the general run of the traffic receipts; but it appears the larger, because during a part of the half year with which we are now comparing the lines were interrupted for a little time. The expenditure also is a little less. That is rather an unusual thing, because with companies that are growing we generally find that the outlay grows with them; but taking the whole together the expenses were in the half-year now under consideration £5,436, or a difference of £80, compared with the corresponding period of the previous year, and that is after making rather an unusual charge for depreciation on stores and cable in stock. You will observe that that amount is £984 for the half-year—rather a large sum. I am not at all sure that it is not too large, but the Board has thought best to err on the safe side, and to bring down our assets to a fully realisable value. Fortunately for us, there has been no interruption of our cables this half-year, and the result is that having no repairs to do we are enabled to increase the reserve fund unusually to meet requirements of the kind which may happen in future periods. Therefore, we have a large sum of £7,000 to add to our reserve fund, which brings it up to £90,000, as compared with £78,000 in the corresponding period of the previous year. The half-yearly payments, I may remind you, regarding the Cienfuegos-Santiago cable of 1881 have now nearly ended. We shall have to make a similar charge in the half-year now current to December next, and a few pounds—about £400 or £500—in the next half-year. It may, perhaps, be desirable to end the whole charge next half-year, and bring in a few hundred pounds to close the whole thing. That charge will then cease to be paid by the Company, and the whole of the cable will then belong to the Company, and will be at their cost to repair instead of the contractors. The feature of the report which is unusual is paragraph No. 5, which relates to the change in the Directorate. Mr. Neil Bannatyne, who was one of the first Directors of the Company, and with whose face you will have been familiar, died some little time since, and the Board had to look about for some one to take his place. At that time Mr. Keith, who has been the manager of our works in Cuba for over fifteen years, was in England, and had intimated his wish to remain in England, and not to go back again to Cuba. The Board at first thought it would be an unwise thing to lose Mr. Keith's services abroad, because they had been so very valuable to us; but Mr. Keith gave us fairly to understand that he would continue to take the same supervision in our cables on the other side, although he might reside in England, as he had hitherto done, and the Board made an arrangement with him, the details of which I will give you presently. It is not necessary to ask you to pass a special resolution; but the Board always feel very anxious, whenever any payment is to be made to them, that the shareholders should be fully acquainted with it. You see a statement in the revenue account of £450, which the Directors receive, and they receive nothing more on any account whatever, whether for travelling or any other expenses; and, therefore, as we wanted to make an additional payment to a Director, we thought it right to inform you. We have made an arrangement with Mr. Keith that, in addition to the £200 which he will get as Director's fees, he shall receive a further sum for taking entire supervision of the cables on the other side as before, and the responsibility of looking after them through the help of one of our servants on the other side. Further than that, I may say that in the event of the cables requiring repair, Mr. Keith has undertaken to go and repair them, receiving during the time he is away from England the same salary he would have received as general manager on the other side. Altogether we have effected a considerable saving, and under these circumstances I think you cannot fail to approve of what the Board has done. If there be any other item in the accounts or the report on which the proprietors desire information, we shall only be too pleased to give it; but pending that, I move—

"*That the report and accounts for the half-year ended June 30th last, now submitted, be received and adopted.*"

Mr. CHARLES W. PARISH: Gentlemen, I have very great pleasure in seconding the motion which the Chairman has just put to you. He has entered so fully into all the matters of interest that we have before us that it is unnecessary for me to enlarge upon what he has already said. I therefore beg to second the motion.

The CHAIRMAN put the motion, and it was carried unanimously.

In reply to Mr. LYDDON, the CHAIRMAN said he could add nothing to the statement in the report respecting the suit against the Spanish Government; and he then proposed—

"*That the following dividends for the half-year be now declared on the shares of the Company, viz., at the rate of 10 per cent. per annum, subject to income tax, on the preference shares, and 8 per cent. per annum, free of income tax, on the ordinary shares, payable on and after to-morrow.*"

Mr. KEITH: I beg to second that.

The motion having been carried *nem. dis.*, Mr. Charles Woodbyne Parish was re-elected as Director and Mr. John Gane was re-elected auditor, and the proceedings terminated with a vote of thanks to the Chairman and Directors.

The Pioneer Telephone Company (Limited).

An extraordinary general meeting of this Company was held on Tuesday last, at Winchester House, Old Broad-street.

The SECRETARY (Mr. J. Cecil Bull) having read the notice convening the meeting,

The Duke of MARLBOROUGH, who presided, said that the Company was formed for the purpose of initiating a new departure in the important industry of telephony, and was extremely well responded to; and he was glad to think that those persons who invested their money in the enterprise were able to realise what, he was sure, they would consider to be a very reasonable profit, having regard to the risk incurred. It was said at the time by certain organs of the Press that the Pioneer Company was simply a sort of *ballon d'essai* for the purpose of finding out what the possibility was of establishing a rival competition to the existing Company. The real object of the Company, however, was to benefit the shareholders and to aid in improving the telephonic system of the metropolis. He had no reason for going back upon that, because he thought that the aims of the Company had been carried out. The Pioneer Company, during the course of its existence, did a lot of very useful work. It made a series of contracts of a very important character, and with a view to a complete London system, it entered, further, into contracts with a company at Manchester, which it acquired. It was, therefore, the possessor of a going concern; and even if the issue of the larger company had been delayed, the Pioneer Company would still have been a good investment for the shareholders, inasmuch as they were in possession of a substantial undertaking in the business of Manchester, which was purchased by the New Telephone Company. It would, perhaps, be hardly opportune for him to enter upon a discussion of the objects of the Company which had been aided by the Pioneer Company, and he would confine himself to a reiteration of the fact that the purpose for which the Pioneer Company was formed had been accomplished. The New Telephone Company had now a real existence, and he might say, speaking very positively, that it would be the means of producing a great improvement in the service of the metropolis, and, in affiliation with the efforts of the National Company, of extending this valuable invention of telephony in other parts of the United Kingdom. The advantage to the shareholders in the New Telephone Company was considerable, by reason of the fact that an alliance of a working character between the National and the New Telephone Companies had been arrived at. There would be no waste of capital in establishing rival systems, while at the same time the demand for this new invention was so large and the field was so vast that there was plenty of scope for the capital of both enterprises. From a public point of view, an advantage also arose, and this was that instead of there being two rival groups of subscribers in different towns, or in the metropolis, subscribers to the one system would be able to talk through the other; and brokers and others would not be obliged to have two instruments belonging to two companies in order to speak to persons possessing the commodity of a telephone. He thought that he would justify the resolution which he was about to put by simply stating what had been achieved, viz., the capitalisation of the New Telephone Company, for the purpose for which the Pioneer Company was originally formed. He now begged to move:—

"*That the Company be wound up voluntarily.*"

Mr. H. PEMBERTON LEACH seconded the motion.

The CHAIRMAN, in reply to Mr. C. EMMOTT, said that the Articles of Association of the New Telephone Company were reconsidered and amended at a general meeting held in the early part of this year, everything being carried out strictly in accordance with the law. The profit of the Pioneer Company largely depended on the success of the issue of the capital of the New Company. When they bought the Manchester undertaking they became the possessors of a paying concern at the time at which it was purchased. They had got 20 per cent. profit on an investment which offered no risk. The sum named as the purchase price of the Pioneer undertaking by the New Telephone Company would cover all contingencies.

The resolution was then agreed to.

Mr. A. A. C. SWINTON moved:—

"*That the Directors be paid the sum of £1,000 by way of remuneration for their services, divisible in such manner as they may determine.*"

Mr. MACKWORTH PRAED seconded the motion, paying a warm tribute to the ability displayed by the Chairman and Directors in conducting the affairs of the Company in the past, as well as in carrying out the negotiations for the larger undertaking.

The CHAIRMAN having briefly expressed his acknowledgments, the proceedings terminated.

Liverpool Overhead Railway Company.

The eighth half-yearly meeting of this Company took place on Tuesday in the Law Association Rooms, Cook-street, Liverpool; Sir W. B. Forwood, Chairman of Directors, presiding.

The CHAIRMAN, in moving the adoption of the report, said that of the total length of railway, comprising 582 spans, all but 35 had been erected. Of these 35, ten were required at the North-end and 25 at the South to

Digitized by Google

complete the entire structure. The material for the parapet and railing which would surmount the structure had already been delivered in Liverpool, but it could not be placed in position until the completion of the laying of the girders. Stations Nos. 3, 4, 5, and 6 had been completed, Nos. 8 and 9 would most likely be finished next week, and the remaining ones were in a forward condition. The permanent way had been laid close to the last girder. At the Wellington Dock the heavy parts of the engines were in place, and would be completed next week, and it would take six weeks or two months to complete the engines. The rails were being placed in position, and other departments were in progress, and they were doing all they could to have the railway completed towards the end of October or beginning of November. He had tried to press the engineers to give them a definite date for the opening. The engineer did not care to do so, but saw his way to having it opened within two or three months. Mr. Cottrell, the gentleman whom they had appointed to manage the railway when completed, an engineer of whom they had the very highest opinion, and who had been working upon the construction of the line for the past eighteen months, was at present in America ascertaining the most efficient and economical system of working by electricity, and he had already obtained some useful and valuable information. With regard to the prospects of the Company, the Chairman believed that the traffic of the line of docks 'buses had increased since the commencement of the Overhead Railway works, notwithstanding the slowness and other disadvantages of that mode of conveyance, so that this was very encouraging for the Company. The powers the Company were seeking, to extend the line to Crosby-road, Seaforth, at the North-end, and Park-road, at the South, had been obtained. The Directors had not received a single application from a shareholder for one of the recently-issued bonds, and the Chairman said he thought the Directors had been well advised to accede to the very advantageous offer of the Bank of Liverpool to place the whole at once. The bonds were taken by the bank at par, the Company paying 1½ per cent. to cover brokerage and all costs of issue.

Mr. R. HOBSON seconded the motion, which was carried; and the proceedings terminated.

Birmingham Central Tramways Company (Limited).

The following is the report of the Directors, to be presented at the general meeting to be held at the Queen's Hotel, Birmingham, on Wednesday next, the 24th inst., at 12:30 p.m.:—

The statement of traffic and profit for the year ending June 30th shows that the profits of the steam department have been materially reduced by the charge for fuel (part of which is exceptional) and by the repairs to engines. The electric department shows a loss chiefly due to the heavy charges for renewal of batteries; but your Directors have now under consideration a contract for maintenance of batteries, which, it is hoped, will tend to material economy and profit of working. The cable department has again shown a gratifying result, and it is evident that upon routes of heavy traffic and severe gradients no other system of traction at present in operation can compete with the steel rope.

The particular attention of the shareholders is directed to the diminution of profit consequent upon the consequent increase of the charges for maintenance, which, under the terms of the leases of the lines within the city as settled by our predecessors, we are bound to pay. How serious these are will appear from the following statements of the amounts paid in successive years:—1885-6, £249. 2s. 6d.; 1886-7, £654. 8s. 7d.; 1887-8, £739. 19s. 6d.; 1888-9, £1,935. 15s. 4d.; 1889-90, £4,683. 0s. 10d.; 1890-91, £5,058. 1s. 3d.; 1891-92, £6,593. 3s. 2d. It is quite clear that so large and increasing an expenditure can only be met by an increased revenue. After careful deliberation your Directors are of opinion that this increase of revenue can be earned by the conversion of the Stratford-road line into a cable line, which would be a source of great profit to the company and great convenience to the travelling public, and would increase the security of the Corporation. They have, therefore, with the concurrence of some of the largest shareholders, applied to the Public Works Committee of the Corporation to allow the expenditure of the whole, or part at least, of the sum of £68,580 (which the Corporation hold as security, and on the bulk of which they allow interest at the rate of 3½ per cent. only) to be applied for that purpose, and they recommend that the committee of the representatives of the shareholders may have authority given to them by the general meeting to assist your Directors in this matter.

The revenue account shows a balance of £17,659. 14s. 11d., to which has to be added the sum of £1,252. 3s. 9d., brought forward from last year's accounts, making together £18,921. 18s. 8d. Your Directors recommend:—(1) That the payment of the dividend upon the Five per Cent. Guaranteed Shares, amounting to £5,000, be confirmed. (2) That the balance of revenue account, amounting to £13,921. 18s. 8d., be carried forward pending the result of the application to the Corporation of Birmingham, above referred to, and also pending the decision of the shareholders as to any reduction of the nominal amount of the ordinary capital.

It has been represented to the Directors by many large shareholders that the time has arrived for reduction of the ordinary share capital from £10 to £5 per share. Diverse views appear, however, to be held upon the subject, and your Directors consider that the authority of the committee of shareholders might, with propriety, be extended to the consideration of this matter also.

Mr. M. J. Smith and Mr. W. Neale (two of the Directors) retire, and, being eligible, offer themselves for re-election. Messrs. Howard Smith, Slocombe and Co. offer themselves for re-election as auditors of the Company.

The working accounts show that the steam trams have run 1,212,624 miles, and carried 14,659,240 passengers, at a cost of a fraction over 1s. a mile; while the receipts have reached nearly 1s. 4d. per mile. The horse cars have earned 11·20d. per mile, and cost close on 10d. a mile. The miles run have been—tramway cars, 131,281; omnibuses, 503,270. Passengers carried—trams, 1,111,607; 'buses, 2,642,134. The cable cars have run 621,210 miles, carried 5,922,304 passengers, earned 12·20d. per mile, and cost 6·18d. per mile. On the Bristol road route the cars have run 188,760 miles, carried 1,382,997 passengers, earned 13·25d. per mile, and cost 15·39d. per mile. Net profit—steam trams, 3·93d. per mile; horse trams and 'buses, 1·24d.; cable, 6·02d.; loss on electric line, 2·14d. per mile. The steam trams have cost £13,155 in fuel and £10,652 in wages (apart from £5,106 paid as wages for repairs); the cable engines have cost only £1,538 in fuel, and £3,874 for the corresponding item of wages.

NEW COMPANIES, STATUTORY RETURNS, &c

COLLIER-MARR TELEPHONE AND ELECTRICAL MANUFACTURING COMPANY (LIMITED).—This Company was registered on August 10, with a capital of £100,000 in £10 shares. The objects are to acquire and take over as a going concern the business and undertaking of the Collier Audible Telephone Syndicate (Limited), and all or any of the assets and liabilities of that Company; with a view thereto to adopt and carry into effect the agreements referred to in Clause 3 of the articles of association (an agreement dated March 17, 1892, between the Collier Audible Telephone Syndicate, Limited, of the one part, and Ernest Hampson, on behalf of this Company, of the other part, as modified by an agreement made between the same parties, and dated August 5, 1892), and to manufacture, construct, erect, maintain, lay down, carry out, buy, sell, let out on hire or on lease, or otherwise deal in telephones and all apparatus and things connected with the establishment, working, and maintenance of telephonic communication or in connection with the generation, distribution, supply, accumulation, and employment of electricity, whether for the purpose of communication, light, heat, motive power, or otherwise, and in particular to construct, erect, sell, repair, and deal in telephones, cables, wires, lines, stations, exchanges, accumulators, and engines. The subscribers (with one share each) are:—Henry Matthews, Darley-street, Manchester; Hubert J. Owen, 14, St. Mary's-gate, Manchester; J. E. Pilling, 27, Leaf-street, Hulme, Manchester; George Graham, 19A, St. Clement's-road, Chorlton-cum-Hardy, Manchester; William Spencer, 322, Manchester-road, Hollinwood; Thos. Chapman, 311, Bolton-road, Pendlebury; William Frost, Spring Bank, Irlam's-o'-th'-Height, near Manchester. Unless otherwise determined, the number of Directors is not to be less than five nor more than seven. Some particulars relating to the issuing of the capital of this undertaking will be found in the CITY NOTES.

RENTON GIBBS AND CO. (LIMITED).—This Company was registered on August 10th with a capital of £10,000, in £5 shares, to acquire the business of heating and ventilating engineer, electrical engineer, &c., carried on at Liverpool and elsewhere by Robert Renton Gibbs.

SPERRYN, McDONALD, AND CO. (LIMITED).—This Company was registered on August 9th with a capital of £5,000, in £10 shares, to carry on in all its branches the existing business of James N. Sperryn, carried on by him at 181, Queen Victoria-street, London, E.C., and at 344, Newtown-row, Birmingham, and to carry on the business of manufacturing and dealing in brass and iron fittings for the electric light, gas, &c.

ELECTRICAL POWER STORAGE COMPANY (LIMITED).—The annual return of this Company, made up to August 3rd, was filed on the 9th. The nominal capital is £100,500, divided into 20,000 ordinary and 100 founders' shares of £5 each. At the time of making up 70 founders' and 18,537 ordinary shares had been taken up, of which 15,000 ordinary shares had been issued as fully paid. Upon the 70 founders' shares the full amount had been called, and upon the remaining 3,537 ordinary shares £3 per share had been called, resulting in the payment of £9,511, and leaving £1,450 as yet in arrears.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended Aug. 14th were £721, as against £653 for the corresponding period of last year, being an increase of £68. The total receipts for half-year amount to £5,424, against £4,952 in the corresponding period of 1891, being an increase of £472.

COLLIER-MARR TELEPHONE AND ELECTRICAL MANUFACTURING COMPANY (LIMITED).—The prospectus of this Company has been issued. The Company is formed with a capital of £100,000, in £10 shares, 2,500 of which are allotted as fully-paid to the vendors in part payment of the purchase money, 2,500 are reserved for future issue, and 5,000 were offered to the public. The total price to be paid to the vendors for the patents and patent rights, and for the Manchester plant, stock in trade and works, which have been erected by the vendor syndicate, is £51,500; this is payable, £4,000 in cash, £25,000 in shares, and the balance partly in shares and partly in cash, or wholly in shares or cash, as provided by the contract. The Company claims for its patents many advantages over the instruments at present in use, one of which is that the patent receiver can be easily attached to existing telephones. The validity of the patents is certified to by Mr. J. Fletcher Moulton, Q.C., and the Company are

Digitized by Google

enabled to commence work at once. Orders have already been received from the Post Office, the Canadian and Indian Telegraph Departments, the Great Northern Railway, the Corporation of Bradford, &c., &c. The list of applications opened on Tuesday last and closed yesterday (Thursday). The Directors are J. W. Maclure, M.P., Mr. Sheriff H. S. Foster, M.P., S. Chesters Thompson, J.P., H. T. Herford, and the patentees, Messrs. Arthur T. Collier and Alexander Marr. The Secretary (*pro tem.*) is J. W. Provis, jun., and the offices and works are situate at Derby-street, Oxford-road, Manchester.

ELECTRICITY SUPPLY CORPORATION (LIMITED).—The Directors have declared an interim dividend for the half-year ending June 30, 1892, at the rate of £5 per cent. per annum on the ordinary share capital of the Company, after payment of all interest on debentures.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended Aug. 12, 1892, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,818.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The estimated receipts of this Company for the fortnight ended August 15, 1892, were £1,982, compared with £1,630 for 1891, showing an increase of £352.

WESTMINSTER ELECTRIC SUPPLY CORPORATION (LIMITED).—The Board have declared an interim dividend for the half-year ending June 30th last at the rate of £3 per cent. per annum.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 745.—Vol. XXIX. FRIDAY, AUGUST 26, 1892. PRICE FOURPENCE. *Annual Subscription (U. K.), 19/6.*

NOTES.

From inquiries at the offices of the North Metropolitan Tramway Company we learn that the accumulator cars which have been running between Barking and Canning Town for more than four years, were suddenly stopped on the 28th of last month by order of the Board, and that the horse service has been resumed.

Accumulator work appears to be ill-fated, whether here or abroad, and no line seems able to live long. This is no doubt largely due to the inherent weakness of the system, but, we cannot help thinking that it is in some measure also due to indifferent financial management. It has been an open secret for years that the Barking electric line has not paid its way; and it is difficult to conceive how it could at 4½d., or even 5½d., per car mile.

At Birmingham also, as was shown in our Notes column last week, the financial results of the accumulator cars have proved unsatisfactory. During 1891-92 the total expenses of these cars have amounted to 15·39d. per mile run, while the receipts only reached 13·25d., leaving a loss of 2·14d. per mile run, or £1,679 on the twelve months' working.

A careful analysis and comparison of the detailed figures given both this year and last by the Birmingham Central Tramways Company, however, puts a different complexion on the matter. Permanent way repairs, which are, it seems, carried out by the Corporation, cost no less than £1,352 last year, or 1·72d. per car mile, as against 0·14d. during 1890-91; an enormous increase due to the Tramway Company having been charged, so we gather, with the wood paving of the entire route. Had this item remained at the same figure per car mile run this year as last, the cars would only have shown a loss of £487. Again, to the fact that the Corporation laid the rails 1½in. out of gauge may reasonably be attributed at least some of the increase of 4·47d. per car mile which is shown this year under the headings of "Electric Haulage" and "Machinery." Had this abnormal increase not taken place the accumulator cars would have shown a profit. It is, therefore, satisfactory to learn that the Birmingham Company does not despair, but has entered into a contract for the maintenance of the batteries at 1d. per mile run.

We publish this week the London County Council's By-Laws relating to Overhead Wires, as finally amended and approved by the Board of Trade. The complete metamorphosis which these much-discussed rules have undergone is at once a tribute to the efficacy of temperate agitation, and to the sweet reasonableness of the Board of Trade; and is, we might add, an indication of the doctrinaire spirit in which the rules were originally framed.

The principal alterations in the by-laws may be usefully summarised as follows:—Owners of existing wires are given six instead of three months' grace to comply with the requirements of the County Council. Instead of having to give a fortnight's notice *before* they erect a wire, companies need not now do so until one month *after*. The maximum span permissible under any circumstances is left open, and is not fixed at 140 yards. It is no longer obligatory to shackle the wires off at every support. The factor of safety for conductors has been reduced from 5 to 4; and although the factor for supports, &c., is retained at 10, the maximum possible wind pressure is taken at 30lb. per square foot, as against 50lb. originally. There is no external diameter limit to cables. Companies are no longer required to take down poles and wires within a month of their going out of use. The rule with regard to the admission of the emissaries of the parochial authorities into houses for purposes of inspection has been, as we have previously announced, almost whittled down into complete innocuity. Finally, four rules are altogether omitted, viz., that which prescribed a minimum angle of 60 deg. for all wires crossing a street; that which allowed no support carrying more than 10 wires to be used by more than one company; that which forbade any single support to carry more than 20 wires; and that which prescribed an efficient earth-connection or a lightning conductor for every pole. The by-laws have gained in weight what they have lost in length.

The record of the performance of two Ferranti continuous-current meters of the very earliest type, which we publish in another column, will be of interest in view of the recent Board of Trade Memorandum, which has been seized upon by the daily press and others as a peg upon which to hang damaging commentaries upon the reliability of electrical things in general. The wear and tear of the mechanism appears to have been an almost negligible quantity, and the constancy of the constant is by no means unsatisfactory when we take into consideration the date of the meters; 1885 is almost in the dark ages so far as electricity supply meters are concerned, so

Digitized by Google

rapid has been their development. Mercury meters have, not without reason, been regarded by many with a considerable amount of suspicion; and it is satisfactory to find that actual experience, at any rate in the case of the Ferranti meter, does not warrant this distrust.

A somewhat sensational paragraph has been going the round of the French papers to the effect that a certain M. Willot has devised a relay which has enabled Paris and Algiers to be placed in direct telegraphic communication, and Hughes and Wheatstone instruments to be worked between these two points as easily as on long land lines. It is unnecessary to say that this is a consummation devoutly to be wished, but we hardly think the time for it has yet arrived. So far as our own information goes all that has been actually accomplished has been to work between Paris and Algiers for a time at about four words a minute. As much as this was done in 1879 by the late M. Ailhaud.

The essence of science is the correlation of facts. We cannot place one brick in a row, at least two are required; nor is there music in one note, though two may make harmony or melody. Similarly, one fact or experiment cannot be accepted as scientific until it is shown to be related to some other. The science lies in the relation, and not in the facts. The effect of an electrical discharge upon a photographic plate has been investigated by more than one experimentalist, but in no case with greater success than by Mr. Campbell Swinton.

The interest of his photographs lies in the difference between the positive and negative discharge; but the photographs tell us nothing but that a difference exists. The difference, which is clearly seen in the illustrations which will be found in another column, does not appear to be related to any of those few phenomena of polarity by which light may some day be thrown on the nature of electricity. Lichtenberg's figures are probably closely allied to these pretty patterns of Mr. Swinton. Until some relation is found between the characteristics shown by these photographs and some other electrical phenomenon, they can hardly find a place in electrical science; nevertheless, every contribution and investigation of this kind must eventually lead to or form the basis of more accurate knowledge, and in this sense they are undoubtedly of scientific value.

It would be difficult for the uninitiated to discover at first glance why the Chairman of the New Telephone Company should have occupied exactly one column of *The Times* of Tuesday last with a letter on the development of the telephone, a letter replete with generalities and well-worn commonplaces about the advantages of efficient telephone service, the backwardness of England, the forwardness of Sweden, and the wonderful advances which are now going to be made. General Webber, however, in a letter in *The Times* of the following day, went to the trouble of putting his finger on what was, of course, the only matter of public concern, namely, the complete *volte face* of the chairman of the New Telephone Company. The vehement representative of the discontent of the telephoning public, the advocate of competition and low tariffs and a telephone in every house, now lays every possible emphasis on the sad effects of competition in general, and of telephonic competition in particular, and on the desirability of high rates in order to keep down the demand for telephones, which, if too large, would prove inconvenient to our present telephonic purveyors. General Webber has done the public a good service in drawing their attention to the true-inwardness of this business.

Only a few weeks ago we remarked that train lighting by electricity presented few advantages over lighting by compressed gas, and observed that accidents from fire or explosion could be rarely attributed to the latter system. A correspondent writing from Buda Pesth subsequently called our attention to one or two rather serious fires; and on Saturday last, in the sad catastrophe at Clapham Junction, a man was burned to death and three coaches were burned to ashes through the ignition of the compressed gas. Several accounts mention an explosion. Experiments have been carried out on gas reservoirs of this kind, with the intent to cause an explosion, but the effect was only the immediate escape, and instant conflagration of the gas. This was, we believe, considered to be a satisfactory result, and the lighting of trains by gas was supposed to be free from danger. The burning of a passenger train appears to be the common sequel to a transatlantic railway accident, and is said to facilitate the clearing of the line; but the scene at Clapham Junction, even though a supply of water and a fire hose were at hand, will probably cause fresh attention to be paid to the possible use on passenger trains of the safest known means of illumination.

Ship Steering by Electricity.—The U. S. monitor "Miantonomoh" was steered by electricity during a recent voyage.

Vienna.—A concession has been granted for the construction of an electric tramway from the Prater to Kagran, a distance of nearly three miles.

The Telegraph in India.—A through telegraph wire from Calcutta to Madras is about to be erected. The length of the new line will be 1,900 miles.

Electric Traction in Belgium.—A Commission appointed by the Minister of Commerce and Public Works to consider the question has unanimously decided in favour of electric traction.

People's Palace Technical School.—Messrs. Slingo and Brooker will deliver courses of lectures on electricity, and other branches of electrical engineering, during the session commencing Sept. 28th next.

American Telegraph Operators.—Amongst the large number of organisations to be represented at a conference to be held in relation to the railway strikes in America is the Telegraph Operators' Union, which is 18,000 strong.

Central Institution.—The matriculation or entrance examination for the Central Institution will be held on September 19th—22nd; and the new session commences on September 28th. Further particulars will be found in our advertisement columns.

The Magnetic Observations of the World.—According to *La Lumière Electrique* there are only 33 magnetic observatories in all in the world. Of these, eight are in France and three in England. About one-half of the total number are provided with Mascart recording apparatus, the others have appliances of the Kew type.

The Cork Gas Consumers' Company.—At the last meeting of this Company the Chairman stated that they had again given notice to the Corporation of intention to apply for an Electric

Digitized by Google

Lighting Order. They were, he said, satisfied that if the citizens wished to have the electric light no one could supply it so economically and so satisfactorily as they could.

The Crystal Palace Exhibition.—"We believe," says *Industries*, "that, taken all round, the Crystal Palace Electrical Exhibition of 1892 has done as much for the progress of the electrical industry as the Exhibition of 1882, and that is saying a great deal. There may be dissatisfaction as to the awards, but there are always complaints of that sort, and anyone who knew the Exhibition will acknowledge that on the whole substantial justice has been done."

Errata.—On p. 430 of our last issue the sentence preceding the table in Prof. Cargill Knott's Paper "On Certain Volume Effects of Magnetisation," should read:—"The numbers are the greatest measured values of the changes of volume. . . ." In the table itself the two last figures in the column headed "Iron Tubes, High Field," should read -37 and -24. The second sentence after the table should read:—"In field 1,000 the dilatation amounted to -6×10^{-6}."

Thunderstorms.—On Thursday, last week, the United Kingdom was visited by a very severe storm, which did considerable damage to property. On Tuesday last, at Langton, Dorset, during a thunderstorm, a cottage, occupied at the time by a woman and her two daughters, was struck by the lightning. One daughter was killed and the mother was seriously injured. Two rooms were completely wrecked, windows, glasses, &c., being utterly smashed.

Electricity in Australian Sugar Mills.—An electrical plant has just been installed in a sugar mill at Bingera (Queensland) by Messrs. Trackson Brothers, of Brisbane. It consists of a 10-kilowatt Firth dynamo, giving 110 volts when running at 900 revolutions, and furnishing current for 70 20-c.p. lamps and 5 250-c.p. Sunbeam lamps. It is also intended to put down a power plant (the first it is said in Australia) using 3 to 6-H.P. motors. An overhead tramway is also projected, which is estimated will prove to be 30 to 40 per cent. cheaper than horse traction.

Antimony in Electrolytic Copper.—Herr W. Hampe states in the *Chemiker Zeitung* that all the specimens of electrolytic copper which he has examined contained a small proportion of antimony ranging from 0·007 to 0·02 per cent. The precipitation of antimony from the copper ore might be checked if the sulphuric acid were not used for so long a time, and thus did not become so highly charged with impurities, but except for laboratory purposes the extra expense involved in the increased consumption of acid would not be proportionate to the advantages gained by the elimination of the antimony.

The Niagara Falls Scheme.—The *Engineering and Mining Journal* of New York states that the Niagara power tunnel will be completed before October 1st, and that it is probable water will be let into it by that date. The other work is progressing rapidly. On August 20th a meeting of the officers and engineers of the Cataract Construction Company was held in New York, and it was expected that Prof. Forbes and Prof. Unwin would be present. The particular business considered was the development of power on the Canadian side and the transmission of power to Buffalo.

Copper.—According to the statement of Messrs. Henry R. Merton and Co., the stocks of copper in England and France and afloat thereto from Chili and Australia, amounted on the 15th instant to 61,831 tons, comparing with 59,738 tons at the end of July, 56,604 tons at the end of June, and 53,965 tons at the end of May. The total supplies for the first half of the current month are put down at 5,521 tons, against 6,357 tons in the corresponding period last month, while the deliveries have fallen from 4,057 tons to 3,428 tons, and the price of bars which stood at £46. 7s. 6d. per ton at the end of May, has declined to but slightly over £44 per ton.

Electric Motors in a Newspaper Office.—We have received a copy of the *Birmingham Daily Gazette*, which has been printed, cut and folded by the aid of electricity. Messrs. Fowler, Lancaster and Co. have put down a complete plant of electric motors for driving two large printing, cutting, and folding machines for producing papers up to 20,000 each per hour. The current is supplied from the mains of the Birmingham Electric Supply Company, and the runs have been most satisfactory. Electricity will be used entirely from now. The proprietors are most satisfied with the adoption of the new power, especially owing to the convenience of its being available at any moment. We believe that the *Birmingham Daily Gazette* is the first daily paper to be so produced.

Lightning Injuries.—We recorded on p. 150 of our issue of June 12, 1891, that a company of soldiers at drill in an open plain near Berlin had been struck by lightning, and that a large number of them had been more or less injured. Dr. Nicolai has lately published in the German *Military Medical Gazette* the outcome of his prolonged investigation of the case. He comes to the same conclusions as many other medical authorities, inasmuch as he holds that the injuries received on this occasion show that, apart from mechanical and calorific effects, life is most endangered by injury to the circulatory system. The peculiar arborescent figures so generally present on the skin of unfortunate individuals struck by lightning are, according to Dr. Nicolai, mainly due to obstructions in, and consequent tumefactions of, the blood vessels. Another fact brought into prominence on this occasion is the marked directional influence of metallic projections such as are frequently met with on the accoutrements and clothing of soldiers.

The Institution of Civil Engineers.—The Council of this Institution invites original communications during the Session 1892-93 on various subjects. The list published is to be taken merely as suggestive, and not in any sense as exhaustive. The following are the electrical papers suggested:—The Cost of Working Electrical Tramways, taking account of interest on capital, and of a sinking fund for depreciation.—The Most Suitable Form of Electric Light Mains, having regard to durability, economy of conducting-material, and facility for making and laying house-connections.—The Risks of Electric Lighting to Life and Property, with the means to be taken to prevent or lessen them.—The Continuous Running of Steam and other Engines, with Details of Construction.—The best Arrangement of Engine for any given Electric Light Station.—Electrical Motors for (*a*) Inland Navigation; (*b*) Ocean Vessels.—The Electro-deposition of Copper.—On the Application of Water Power and its Transmission to a Distance by Electricity.—The Design of Electric Locomotives.—The Practical Working of Multiphase Alternating-Current Motors.

An Electric Locomotive for Mining Purposes.—An electric mining locomotive has recently been made by the General Electric Power and Traction Company, and is part of a large installation supplied to the Greenside Mining Company, Cumberland. The road on which the locomotive must run being in some places as narrow as 32in., the gauge of rails being 22in., it was found impossible to place the motor across the frame, so its shaft was arranged parallel to the rails. Three reductions are employed, one necessarily being through bevel gearing. The whole framework of the machine is hinged from the driving axle, which is made exceptionally strong for the purpose, the weight on the other wheels being taken through strong spiral springs on the top of gun metal axle brasses. The motor is series wound for a difference of potential of 200 volts, and develops 15 brake H.P. at 1,000 revolutions per minute. The length of the road is 1,200 yards, and the current is collected from two bare copper wires carried on insulators overhead. The E.M.F. is reduced from 500 volts to 200 volts by means of a motor transformer placed at one end of the line. Water is the prime source of power.

Exports of Telegraphic Apparatus.—The Board of Trade Returns for July were disappointing, showing a combined decrease in the exports of nearly £2,500,000, of which nearly £600,000 was under the head of metals and articles manufactured therefrom. The figures relating to the exports of telegraphic wire and of apparatus connected therewith, were also disappointing. The monthly figures frequently vary considerably. For instance, the total value of the exports in March was less than £19,000, whereas in the following month the exports were valued at over £447,000. This great divergence is naturally due to the special character of the trade, which involves at times very heavy shipments in connection with the

Digitized by Google

execution of large contracts. The July exports, however, were poor, as showing a very small total following a very small total in June. The aggregate exports for the seven months to date are the smallest of the past three years. The following is a comparative statement of the exports for the first half of the past three years, and for July :—

	1890.	1891.	1892.
January to June	£721,712	£984,530	£675,835
July	56,575	150,754	25,906
Seven months	£778,287	£1,135,284	£701,741

The Chicago Exhibition.—The following Reuter's telegram, dated Chicago, August 22nd, is interesting :—

Although the appropriation made by Congress for the World's Fair was reduced during the debate in the House of Representatives from $5,000,000 to half that sum, the result will, it is believed, be extremely satisfactory to the managers of the Exhibition. The money was granted in the form of five million special souvenir silver coins of the weight, fineness, and value of the regular silver half dollars in current use. As soon as it became known that the souvenir coins were to be issued to the Fair officials from the United States Mint at Philadelphia, there was an immediate demand for them from all parts of the country. It at once became apparent that the coins could be disposed of by the Exposition at a large premium. The editor of a leading New York newspaper offered 100 per cent. premium for 10,000 coins. Merchants and bankers made similar offers, and during the five days succeeding the passing of the Bill tenders were received for 600,000 of the coins at 100 per cent. premium. A syndicate of bankers in the West offered to take the entire issue at 60 per cent. premium. High offers have also been made for the first souvenir coin struck at the mint. A Chicago newspaper started the bidding at £25, but several wealthy men in Chicago have expressed their intention of securing this coin if it cost £200. It is probable that the coin will be sold at public auction in Chicago, a certificate from the Director of the Mint going with it to guarantee that it is the only genuine first souvenir coin. It is probable that all the coins will be sold by the World's Fair management at 100 per cent. premium, and that the Exposition will thus double the appropriation.

The Thermodynamic Value of Town Refuse.—At the present moment, when the employment of the heat produced by the destruction of town refuse for generating steam for electric lighting purposes is before the scientific world, the following extract from a paper read before the Liverpool Engineering Society, by the City Engineer of Liverpool, Mr. Percy Boulnois, may be usefully reproduced. Mr. Boulnois stated that he had received some valuable information from Mr. B. H. Thwaite, on the subject of the thermal value of house refuse, from which the following was abstracted :—"The thermal value of the organic matter has been rigidly tested by the calorimeter; and the net value available for external thermodynamic work may be expressed by the formula $Y = \left(\frac{X \times 2 \times 80}{20}\right) \times 1{\cdot}25$, where Y represents the net available thermal value for motive power purposes; and X represents the corresponding value of coal. For instance : two pounds of coal is required for providing the motive power equivalent to one brake-horse power per hour; the amount of refuse that would be required to effect the same dynamic effect would be $\frac{2 \times 2 \times 80}{20} \times 1{\cdot}25 = 20$lb., or ten times the weight of coal required to do the same work. The factor 1·25 is arbitrarily fixed to represent the internal work of evaporation and self-destruction. The proportion of water in organic vegetable matter may vary from 10 per cent. to 90 per cent."

A Polarisation Experiment.—At a recent meeting of the Physical Society of Berlin, Herr Arons described the following experiment on electrolytic polarisation. If we divide an electrolytic vessel with platinum electrodes and acidulated water solution by a partition of some precious metal, such as gold, silver, or platinum, a diminution of current is usually observed; and the metallic partition will be hydrogen polarised on one surface and oxygen polarised on the other. Herr Arons experimented with a view to seeing whether he could obtain a thin enough partition for the two polarisations to annul one another. He employed for this purpose an electrolytic vessel 22cms. long by 5 broad and 8 high, divided in the middle by a sheet of glass pierced by a hole 1·5cm. in diameter. When the sheet of glass with an unobstructed opening was replaced by one which had the opening covered by a piece of platinum foil 0·1mm. thick, the deflection of the galvanometer was diminished, and there was a violent ebullition of gas. Gold and silver leaf partitions caused no disturbance. By altering the resistance out of the galvanometer circuit its deflection was in each experiment brought back to its original value. The following figures give the resistance which it was found necessary to take out of circuit in each case :—Solid Pt plates, 19 ohms; Pt plate pierced with a hole 3mm. in diameter, 5 ohms; Ag and Au (leaf), 0 ohm; four layers of Au leaf superposed 0·25 ohm.

The Absorption of Radiant Heat.—In the *American Journal of Science* for June Mr. C. C. Hutchins has a Note on the "Absorption of Radiant Heat by Alum." It seems, he says, to be the generally accepted opinion that a solution of alum acts as a particularly efficient absorber of rays of great wave length. Whence this idea in regard to the effect of alum solution arose it is difficult to say. Melloni's table, as far as it goes, shows that bodies in solution raise slightly the percentage of transmitted rays above that which passes through pure water. Mr. Hutchins prepared a saturated solution of potash alum in distilled water, and placed it in a cell 0·6cm. thick. The sides of the cell were quartz plates 0·15cm. thick. The heat-measuring apparatus was used to determine the transmission of the rays from a naked gas jet through this cell. The mean of 10 galvanometer readings was 201 divisions. The cell was then filled with pure water, and the mean of ten readings found to be 196 divisions, showing, if anything, that water is a slightly better absorber than alum solution. When two hundred ohms resistance were added in the galvanometer circuit, the deflection produced by the unobstructed gas jet was 240 div. Through the water cell it was 21·5 div. and the per cent. transmitted was 8·9. When a sheet of plate glass 0·7cm. thick was interposed the deflection was 86 div. and the per cent. transmitted was 35·8. A crystal of alum was then found from which a nearly flawless plate was cut. The plate was given a perfect polish on both sides. The plate was 0·37cm. thick, and the deflection of the galvanometer by the gas jet through the plate was 23·4 div., and the per cent. transmitted 9·7. Hence it appears that a solution of alum is no better absorber than is water; and furthermore, that it would hardly pay to use plates of transparent alum, even if they were to be had.

Spanish Telegraph Reforms.—Stimulated possibly by the recent serious strike of telegraph *employés*, the Spanish Director-General of Communications is drawing up a new scheme for the entire re-organisation of the Postal and Telegraph Service, and the various telegraph and technical papers in Spain are actively discussing the proposed reforms. These are, for the most part, of a technical character, and of little interest outside the *personnel* of the Spanish telegraph service. One subject, however, has been brought forward of more general interest, namely, the idea of a system of military telegraphic communication. It has been recognised that, from a military point of view, the Government might be placed in a very serious position at a critical moment in the event of an interruption of communications such as that which the trading community recently had to put up with. It is argued that the question of military telegraphs has become urgent. The Madrid *Dia* is of opinion that the Minister of War should immediately take the subject up with a view to placing the capital of the Kingdom in communication with the principal interior and frontier stations. Our Madrid contemporary considers that the Government might make use, to begin with, of the general telegraphic system, and also avail itself of the railway telegraphs, if only as a temporary measure, until the fuller scheme in all its extensions might be thoroughly carried out.——According to latest advices the Queen Regent of Spain has signed at San Sebastian a Royal decree by which the fusion of the postal and telegraph services of Spain, as established by the former Director-General Señor Don Xavier Los Arcos, is cancelled, and all the rights and privileges of the telegraph department re-established. A certain number of the oldest telegraph officials have been pensioned, and this has enabled the Minister of the Interior to promote a large number of younger men to higher positions. Forty-five inspectors of lines have been appointed, and, generally speaking, steps have been taken by the new Director-General, Señor Don Federico Arrazola, to improve the telegraph service in Spain. The telegraph corps have thus gained all the points they fought for.

A NATIONAL PHYSICAL LABORATORY.

Great Britain has certainly no need to boast of her supremacy in science, if, at a time of so much scientific activity on all hands, she allows neighbouring nations to take giant strides in the organisation of scientific research and in the establishment of bureaus of scientific measurement, without making at least the attempt to possess herself of similar advantages. It is true that the Royal Observatory of Greenwich has for long done standard scientific work for the conjoint sciences of navigation and astronomy; and that, more recently, the Kew Observatory has been modestly doing the same kind of work for the science of meteorology. Further, the Board of Trade has lately set up a tiny laboratory for the testing of electric supply meters. Yet we seem to be as far removed as ever from the creation of a proper National Physical Laboratory. Such an institution as this, devoted to the double end of organised research and the application of research to the production and verification of standard instruments, would undoubtedly prove of enormous benefit. Just as the existence of Greenwich Observatory has reacted upon the trade of chronometer making (not to speak of other scientific trades allied with navigation and astronomy) by furnishing a test of merit, stimulating rival makers toward the attainment of perfection, so the establishment of a National Physical Laboratory would exercise an equally beneficial, and even more widely-reaching influence upon the various scientific industries that have been growing up in recent years. Should any one doubt this proposition let him learn from the four years' history of the Berlin Reichsanstalt what such an establishment, under the direction of von Helmholtz, has been able to do for Germany. Let him consider what is the significance of the single fact that to that establishment no fewer than 20,000 thermometers are now sent every year to be verified and certificated. Let him read in our pages the account of the researches therein made on alloys suitable for electric resistances, on glass of kinds suitable for scientific purposes, on the proper methods of hardening and tempering steel, and on numerous other practical problems of enormous industrial importance. Then let him ask himself why is it, how is it, that we in England have no such establishment to benefit our industries at home? Why is it, and how is it, that we leave scientific research to the chance leisure of the overburdened teacher or to the tender mercies of the wealthy amateur? Why is it and how is it that a great department of Government, to which is entrusted the spending of millions of money for the purposes of science and art, spends that money almost exclusively on the most elementary sort of teaching of the uninstructed—of the cripples, so to speak—rather than on either the higher teaching of those who have proven themselves to be capable or on the still higher end of research? Research, when conducted by the amateur, tends undoubtedly too often to become amateurish. It is, perhaps, because he has some perception of this that the average Briton is apt to sneer at the advocate of the endowment of research, as one who is only engaged in a research for endowment. But research conducted on an organised plan in a properly equipped building, where research, and nothing but research, is the aim, is a wholly different thing from research carried on by professors during their holidays, or during hours snatched from teaching in a corner of a laboratory organised for instruction rather than for research. It is also a wholly different thing from the, perhaps, too discursive efforts of the wealthy scientific amateur. Our universities, university colleges, and even our technical colleges, have done something from time to time to supply, though but imperfectly, the national want. But there is much which, even if they were better endowed and equipped, they could not do, being organised essentially and primarily for instruction. Let this be fully and fairly recognised once for all. There is work to be done for which an institution is urgently needed that shall not be a teaching institution. No one pretends that Greenwich Observatory is a place for instruction; it was not founded for educational purposes. An observatory is intended for the purpose of making observations—in other words, for astronomical research. What is wanted now for England is a Physical Laboratory, equally relieved from any educational taint or burden, intended as a place for physical observation and equipped as perfectly as modern science will permit for that end.

Prof. Oliver Lodge, who has now for several years stood prominently forward as the champion of such an institution, has shown in some detail in what work it might fitly engage. The preliminary programme of researches which he lays down is enough to tax all the resources of such a laboratory for 20 years to come, quite apart from any such subordinate functions as the standardising of instruments or the custodianship of standards of measurement. If there is urgent need in the scientific and industrial world for researches of such magnitude, there is surely no time to be lost in half measures. Electric science has more to gain than any other in the immediate future by the establishment of a National Research Laboratory. Let the example of Germany spur us on, not to servile imitation, but to the creation of some institution to meet our own needs in our own way. Let every electrician arouse himself, and endeavour to arouse our lethargic politicians into a sense that there are other questions of importance besides even such questions as technical education and the proper way of governing a neighbouring island.

THE BRITISH ASSOCIATION—CONFERENCE ON ELECTRICAL STANDARDS.

The causes which led to the Conference on Electrical Standards at Edinburgh may be briefly stated. Prof. von Helmholtz wrote to Lord Kelvin in May last to express the hope that an absolute uniformity might be obtained in England and Germany with regard to electrical standards adopted as legal in the two countries. Lord Kelvin, with the cordial assent of those members of the British Association Committee to whom he was able to mention the matter, invited Dr. von Helmholtz to Edinburgh to discuss the question involved; and when it was known that he would accept this invitation and bring with him two of his assistants, Dr. Lindeck and Dr. Kahle, invitations were sent to the Bureau International at Paris, and to Prof. Rowland at Baltimore. M. Guilleaume kindly responded to the invitation. Prof. Rowland was unable to come, but the committee had the assistance of Prof. Carhart, who furnished them with valuable information in regard to the Clark cell. A Paper of agenda, which has already appeared in *The Electrician* (July 29, p. 337), was issued by the secretary.

The first subject discussed was the dimensions of a column of mercury which has a resistance of one ohm. Prof. von Helmholtz called special attention to the difficulty of defining the cross-section of a lens column in terms of the square millimetre, because the mass of a cubic centimetre of water is not accurately known in grammes; and the cross-section of the narrow thread has to be found from its mass and its length. He pointed out that this could be met by defining the mass of the column of given length which should have the required resistance, and it was agreed to define this mass in such a way that, assuming the mass of 1 cubic centimetre of water to be 1 gramme, the area of the cross-section should be 1 square millimetre. M. Guilleaume mentioned the results of recent experiments at the Bureau International in the relation of the gramme and the centimetre, and expressed his agreement with Dr. von Helmholtz's suggestion.

The experiments by which the length of the column had been determined were then considered. In this discussion the Committee were aided by the results of an exhaustive criticism of existing measurements by Dr. Dorn, which was communicated by von Helmholtz. This it was understood will be published shortly. In the end it appeared that 106·3 cm. might be taken as the length of the column, with an accuracy of nearly one part in ten thousand. So far, except in regard to the exact manner of defining the cross section, the results agree with resolution No. 4 of the Board of Trade Committee, which runs thus:—"That the resistance offered to an unvarying electric current by a column of mercury of constant cross sectional area of one square millimetre, and of a length of

Digitized by Google

106·3 cm. at the temperature of melting, &c., may be adopted as one ohm."

The next question dealt with was the means of practically realising the standard of resistance; and here a distinction must be drawn between a practical unit of resistance and a "legal standard" of resistance. A "legal standard" is some concrete object, a coil of wire for example, which has a definite property, viz., in this case that its electrical resistance under certain conditions is one ohm. Various objections have been raised against making a tube of mercury the "legal standard" of resistance, and accordingly in the Board of Trade Committee Report a material standard constructed in solid metal was adopted. This material standard was to have the same resistance as the column of mercury, but it was to be constructed and verified by comparison with the British Association units. Moreover, if lost, destroyed, or damaged it was to be replaced through the British Association units. Practically, then, these became the units of resistance, and the question of their permanence was one of great importance. The discussion showed that this mode of obtaining the legal standard and checking variations which might occur with time would lead to difficulty, and in the end it was agreed to omit all reference to the B.A. unit in the resolutions. Dr. von Helmholtz described some recent experiments of Dr. Kreschgauer on the resistance of mercury tubes; it also appeared from comparisons made at Cambridge, just previous to the meeting by Dr. Lindeck and Mr. Glazebrook, that coils of wire constructed in Berlin and Cambridge respectively to represent one ohm agreed to about one part in ten thousand; while the mercury tubes constructed by M. Benoit had been shown to agree with those made in Cambridge to about the same degree of accuracy. It was clear, therefore, that a standard in solid metal having the same resistance as the specified column, could be made with considerable exactness, since such standards made at various places agreed so closely, and it was urged that such a standard could at any future time be recovered with greater certainty than was possible if reliance was placed on a wire coil to which an accident might happen even if it were free from secular change. As a result of the discussion the following resolutions were adopted :—

1. That the resistance of a specific column of mercury be adopted as the practical unit of resistance.
2. That 14·4521* grammes of mercury in the form of a column of uniform section 106·3cm. in length at 0° C. be the specified column of mercury.
3. That standards in mercury or solid metal having the same resistance as the specified column be made and deposited as standards of resistance for industrial purposes.
4. That such standards be periodically compared with each other, and also that their values be redetermined at intervals in terms of a freshly set up column of mercury.

Dr. von Helmholtz expressed his complete agreement with these resolutions, and explained that they were in accord with the proposals laid by himself and the Curatorium—the consulting committee—of the Reichsanstalt before the German Government; while M. Guilleaume, in welcoming the decisions, expressed the opinion that the French Government would concur in the recommendations.

The Committee then went on to consider the question of the electrolysis of silver. The Secretary read the clause of the Board of Trade report dealing with this, viz., "That an unvarying current, which, when passed through a solution of nitrate of silver in water, in accordance with the specification attached to the report, deposits silver at the rate of 0·001118 of a gramme per second, may be taken as a current of 1 ampere." The terms of the specification were described, and Dr. Kahle gave an account of his repetition of Dr. Schuster's experiments on the effect of the oxygen dissolved in the solution. He has shown also that by making the solution basic the mass of silver deposited is slightly increased. After further discussion Dr. von Helmholtz stated his opinion that the resolution which had been read expressed the result of experiments made up to the present with all the requisite accuracy, it was therefore accepted.

* The value of the specific gravity of mercury at zero is 13·5956. This multiplied by the length 106·3cm. and the nominal area ·01 sq. cm. gives 14·4521 as the mass.

With regard to the Clark cell, Dr. Kahle described his recent investigations. An account of these, together with his remarks on the electrolysis of silver, and Dr. Lindeck's results on resistance coils of magnesium, will, it is hoped, be printed as an appendix to the Report of the Standards Committee. Dr. Kahle has found for the E.M.F. of the cells issued as standards by the Reichsanstalt the value 1·4341 volts at 15deg.; his H-form cells are somewhat lower. The values found by Lord Rayleigh, Prof. Carhart and Mr. Glazebrook respectively are 1·4345, 1·4340 and 1·4342 volts at 15°C. The numbers were confirmed by a comparison between Dr. Kahle's cells and those at the Cavendish Laboratory, made just previous to the meeting by Mr. Glazebrook. It was agreed that the number 1·434 volts at 15deg. might be taken as the E.M.F. of the cell.

The outcome of the Conference has thus been that the desire expressed by Dr. von Helmholtz for uniformity of standards is in a good way to be realised so far as France, Germany, and England are concerned, while the assurances given two years ago at Leeds by Prof. Rowland and Prof. Barker, make it practically certain that the same numbers will be adopted across the Atlantic. Should these hopes be fulfilled, the Edinburgh meeting of the Association will be long remembered as one at which work of the very highest importance to electrical science has been accomplished.

ON A MAGNETIC BALANCE AND ITS PRACTICAL USE.*

BY DR. H. E. J. G. DU BOIS.

In a Paper on "Magnetic Circuits and their Measurement," read to the Frankfort Electrical Congress in 1891,† the principles of a magnetic balance were explained, with which magnetic curves of any material might be readily obtained in absolute measure. It may be theoretically defined as an electromagnetic system of variable configuration, the reluctance of which always naturally tends towards a minimum; its variations however remaining exceedingly small. I now propose to describe the instrument exhibited to the Section.

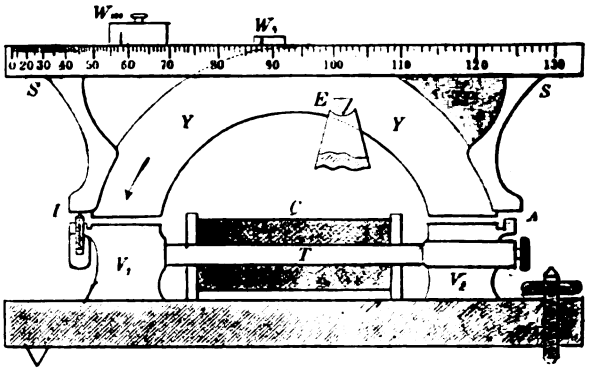

FIG. 1.—Du Bois Magnetic Balance. Diagramatic View

It is the outcome of a year's evolution of constructive detail. By means of a gauge belonging to the instrument, one test-piece T is cut to 15cms. length and 1·128cm. diameter, corresponding to 1 cm.² section; the latter need not necessarily be adhered to, if inconvenient, but has the advantage of obviating all further calculations, as will be seen below. The coil C is 4π cms. long,‡ and wound with 100 turns; therefore, near the middle it gives a field = 10 × current (in amperes). It will carry currents up to 30 amperes, which may be conveniently measured by the usual ampere-meters. The corresponding range of field (0 to 300

* Read before British Association, Section A, Edinburgh, August, 1892.
† *The Electrician*, Vol. XXVII., 1891, p. 634.
‡ Really it is slightly shorter (12·2cms.) to compensate the end effect.

Digitized by Google

C.-G.-S.) is all that is wanted in the great majority of cases. The test-piece is supported on two adjustable M-plates, by means of which it may be readily set concentric to the coil, which is then slipped into position, the test-piece being automatically clamped by the plunger in the upright V_2. Fig. 1 (a quarter of the natural size), shows the curved yoke YY of best Swedish iron playing over the stop A and screw I. The latter is enclosed in a cap after calibration, so that the adjustment cannot be interfered with. P is a lead counterweight. Fig. 2 gives a perspective view of the instrument.

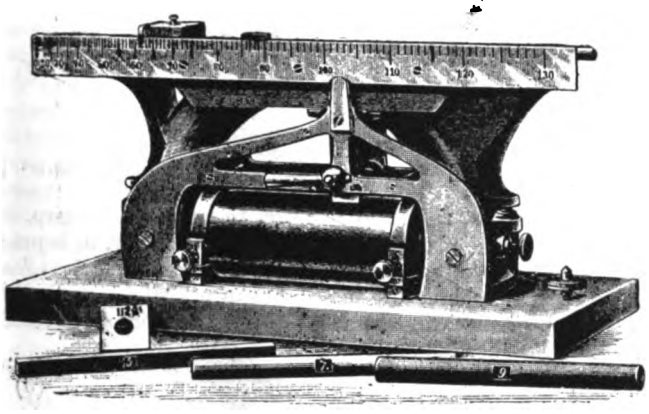

Fig. 2.—Du Bois Magnetic Balance.* Perspective View.

I have made a series of observations to find, experimentally, what function of the magnetisation of the test-piece the resulting moment on the yoke (measured by compensating with the sliding weights) would prove to be. A small secondary was slipped over the middle of T and connected to a ballistic galvanometer. It was found that the resulting moment was accurately proportional to I^2 (or B^2) up to values of $I = 1{,}300$ (or $B = 16{,}000$), with a test-piece of 1 cm.^{2} section; this is all the range that is usually wanted; however, by using a somewhat thinner sample, magnetisations up to 1,700 C. G.-S. may be measured, as the tractive forces really depend upon the flux of induction through the test-piece only.

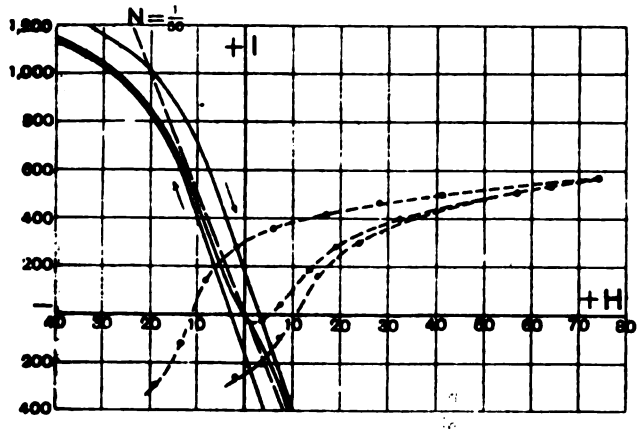

Fig. 3.—No. 7 Ordinary Cast Iron. 25,000 ergs per cm.^{3} Coerc = 11.

After this law had been experimentally established, it was evidently better to introduce a quadratic scale. Along this two mutually independent weights, W_{100} and W_4, slide, of 100 and 4 grammes weight respectively. Accordingly, the scale-readings have only to be multiplied into the square roots of those weights, viz., 10 or 2, in order to obtain the absolute value of I in the sample. The smaller weight is used for the range of $0 < I < 260$; it is then slid back to zero, and measurements continued with the larger weight for $260 < I < 1{,}300$. The instrument does not indicate whether one is to take $+\sqrt{I^2}$ or $-\sqrt{I^2}$; but on plotting the results this becomes at once evident, one of the two points falling entirely outside the smooth curve representing the observations; it is therefore unnecessary to add a special permanently polarised arrangement, with which to detect the direction of magnetisation.

The demagnetising factor N for a cylinder of dimensional ratio (length/diameter) 15 is about 0·12;* it is found in the balance to be reduced to 0·02, corresponding to the threefold ratio 45. This number was found by plotting the curve of a standard sample directly from the balance, and shearing it backwards into coincidence with the normal curve obtained with a ring of the same material. The result was, moreover, arrived at that the usual rectilinear pseudo-axis of ordinates

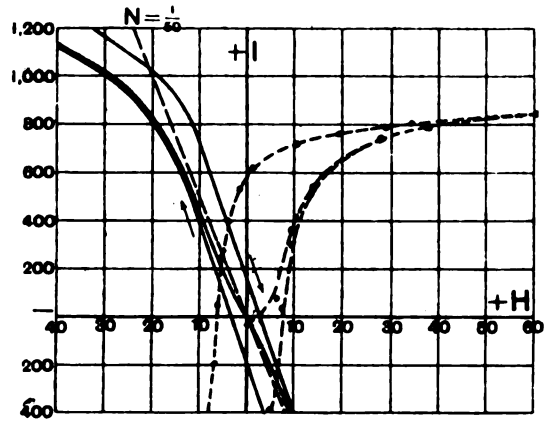

Fig. 4.—No. 6 Malleable Cast Iron 24,600 ergs per cm.^{3} Coerc = 7.

would do well enough up to half the saturation value; but that on the whole it was more accurate to introduce a generalised curvilinear shearing-base. This may be called an instrumental directrix, as it remains characteristic of the instrument when once determined by means of a standard sample; all the corrections due to the uprights V_1 and V_2, the yoke Y Y, the air-spaces with their variable leakages, &c., are combined in it; it is used when ordinary unlooped curves of ascending reversals are being taken. In order also to correct for hysteresis of instrumental parts of the magnetic circuit, it is advisable to introduce two other directrices, the horizontal distance of which

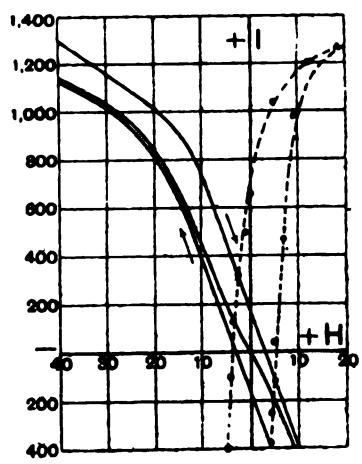

Fig. 5.—No. 9 Iron Wire (Annealed). 20,000 ergs per cm.^{3} Coerc = 4.

measures the coercive force of the apparatus. The left one is used for plotting ascending curves, the right one for the descending branches.

In conclusion, I may offer a few remarks on the practical use of the magnetic balance. The coil is placed in circuit with a reversing key, a good ampere meter, one or two storage cells and rheostats (preferably liquid), so as to admit of easily and gradually reversing, varying and reading the current between 0 and 30 amperes. In the first place, everything should be thoroughly demagnetised by diminishing reversals; accordingly, the yoke is slowly lifted by an arrangement provided for the

* *See* the table in my "Mathematical Theory of Ferro-Magnetism," *Wied. Ann.* XLVI., 1892, p. 498.

Digitized by Google

purpose, while the reversing key is being quickly worked; it ought to remain in the lifted position when the instrument is not used, in order to spare the knife edges E. Then the coil is moved towards the observer and the test-piece gradually pulled out, reversing all the time.

The method of taking readings will be sufficiently obvious from the above description; I will only add that on account of magnetic instability the position of the sliding weight is determined, which will just pull the left-hand stop off the screw I; it has been found an unnecessary complication to introduce a secondary bell or telephone circuit as a criterion for the breaking of contact. The observer's ears and fingers afford a readier means, and after some little practice different observers always find exactly the same reading to one or two-tenths of a scale division (corresponding to a unit of magnetisation); this is more than sufficiently accurate.

The tenfold ampere and scale readings (or with the small weight only double the latter) directly give abscissæ and ordinates respectively in C.-G.-S. units. The former are measured from the instrumental directrices as explained above; these are drawn on a transparent card belonging to the instrument, which is laid on the upper left-hand or lower right-hand quadrant of the squared paper, the plotting on which is thereby rendered as simple as when the usual method is followed. If the section of the test piece is not 1cm.^{2}, it has to be measured, and the ordinates have still to be divided by it *after* the above process of plotting.

The dotted curves of Figs. 3, 4, and 5 were obtained with actual samples in the instrument exhibited. The full-drawn lines are the directrices; the middle one for ascending reversals is seen to considerably deviate from the straight line corresponding to $\mathbf{N} = 0{\cdot}02$ as the magnetisation increases beyond 850. From the malleable iron curve (Fig. 4), the first given for this material so far as I am aware, it may be inferred that its magnetisation (for $\mathbf{H} = 65$) is about 50 per cent. greater, and its coercive force as much less than those of ordinary cast iron. Fig. 5 was obtained with a bundle of 124 thin iron wires, presenting a total cross section of 1cm^2.

ON LEAKY MAGNETIC CIRCUITS.*

BY DR. H. E. J. G. DU BOIS.

Ever since the Hopkinsons' researches a great many experiments on magnetic circuits have been made, mostly, however, in the form of measurements on dynamos of various types. Now the results obtained with a particular dynamo may offer a certain degree of interest, especially to its maker; but the utmost care has to be taken in generalising from such data. Quite apart from the consideration that ballistic measurements on dynamos suffer under the undue proportion their time-constant bears to the period of even the slowest ballistic galvanometer, dynamo circuits are not designed for giving interpretable scientific results, but for economy. For all these reasons it seemed to me a useful thing to thoroughly overhaul the whole subject by theorising and experimenting on the simplest conceivable type of magnetic circuit. And though the subject of these circuits has been amply discussed for the last ten years, I venture to hope that its importance may warrant my bringing the first results of this rather lengthy investigation before Section A.

Consider a split-ring magnetised by a uniform peripherical field. Let r_1 be the radius of the central circle, r_2 that of the circular section, d the width of the air-gap. Assuming, then, as a first approximation that the magnetisation is uniform over the whole section of the ring and its direction everywhere peripherical, it may be shown† that

$$\mathbf{N} = \frac{2\,(d + r_2 - \sqrt{d^2 + r^2_2})}{r_1 - \frac{d}{2\pi}}, \quad \ldots \quad (1)$$

where $\mathbf{N}$ is the well-known "demagnetising factor," which determines the amount of shearing over of the magnetic curves.

According to a theorem first given by Kirchhoff, the above state of affairs will strictly occur when the external magnetising field becomes infinite; the direction of the lines of magnetisation is then bound to coincide with that of the applied lines of force. The values of $\mathbf{N}$ actually found must, therefore, approximate to those given by (1) as the field increases.

For less strong fields an exact calculation is impossible; but it may be stated that in this case

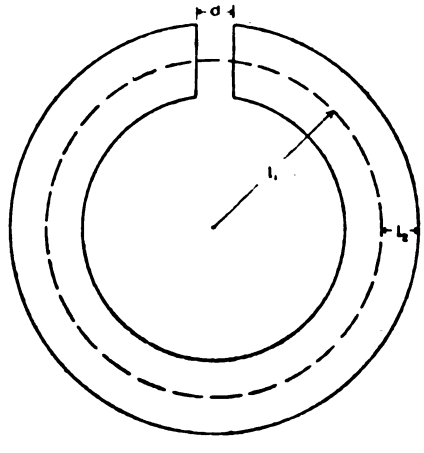
$$\mathbf{N} = \frac{2\,d\,n\left(\frac{d}{r_2}\right)}{r_1 - \frac{d}{2\pi}}, \quad \ldots \quad (2)$$

where the functional notation $n\left(\frac{d}{r_2}\right)$ means a number which is a function only of the ratio of width to radius of air-gap, independently of the rest of the circuit. This number, n, is practically equal to the reciprocal of the "leakage coefficient" as defined by the Hopkinsons.

It may be remarked that both the expressions given converge towards the simple form

$$\mathbf{N} = \frac{2\,d}{r_1}, \quad \ldots \quad (3)$$

when the width of the air-gap diminishes more and more towards zero. In this case the value of n is unity, whereas for wider gaps n becomes a fraction. Moreover, the number n, as well as the factor $\mathbf{N}$, vary somewhat with the magnetisation in a way which it must be left to experiments to determine.



These were carried out under my advice by Mr. H. Lehmann. A ring, about 15cm. mean diameter and 2cm. thick, was turned out of best Swedish plate, and well annealed. It was wound uniformly all round with primary and secondary wire, and its normal curve first taken in the unsplit state. It may be remarked that curves of ascending reversals were taken throughout, the thickness of the iron giving so much time-lag that the step-by-step process would not give correct results. The magnetising field could be pushed to 400 C.-G.-S., the ring being immersed in a trough of iced petroleum.

The ring was now cut, beginning with a very narrow gap of a few tenths of a millimetre width. A small brass disc was fixed in the gap to prevent the iron from yielding to magnetic attraction, and a small secondary wound so as just to enclose the lines of induction crossing the air. Another auxiliary secondary coil could be moved around the ring so as to explore the leakage. The general results may be summarised as follows:—

(1) For the very narrowest gaps the formula (3) holds, as it should.

(2) As the width increases (2) becomes applicable; the values of n found from the throws due to the auxiliary secondaries, when substituted into (2), give numbers for N in good agreement with those found by the "shearing backwards" graphical process.

* Paper read before the British Association in Section A, Edinburgh, August, 1892.

† *See* "Mathematical Theory of Ferro-Magnetism," *Wied. Ann.*, XLVI., 1892, p. 494.

Digitized by Google

(3) Both n and N remain practically constant up to values of I about half the "saturation" value, *i.e.*, 850 C.-G.-S.; for higher magnetisations they begin to show an *increase*, N approaching to, but not superseding, the value given by (1), as was theoretically predicted above.

(4) As a rule, the *mean* magnetisation was deduced from the throw due to the principal all-round secondary; this was almost identical with the result given by the auxiliary secondary when diametrically opposite the air gap, and by further exploration with this secondary it was found that an appreciable leakage began to occur only at about one-eighth of the circumference on both sides of the gap.

The numerical values of n within its range of constancy (which is the range of magnetisation mostly worked with) are of general interest because they, or their reciprocals, depend only upon the ratio of width to radius of air-gap, as explained above. Moreover, it will hardly matter much whether the section of the gap be exactly circular, so long as its area be the same; we thus obtain numbers of a certain utility in all questions of design where air-gaps occur. I prefer not to give the actual figures here; they being liable to slight corrections; they will soon be published in full in *Wiedemann's Annalen*, together with the experimental detail.

The result (3) that n finally *increases* with I, I consider to be fully proved by experiment; it corresponds to a final *decrease* of its reciprocal, the leakage coefficient. Now this is in complete disagreement with what is generally accepted as a dogma, viz., that leakage becomes more and more pronounced with larger inductions. This fallacy, as I cannot now help calling it, has generally been explained by the fact that the permeability of iron decreases, and so becomes more equal to that of the surrounding medium. If, then, Ohm's law held there is no doubt but that more leakage would occur. But a true ohmic law does not hold in magnetism; or rather the excellent results obtained by applying it in particular cases do not warrant its generalisation. Its complete failure to predict or explain in the present typical case may be hoped to bring home a little more care in its manipulation to those liable to grow too enthusiastic about magnetomotive force and reluctance.

On the other hand, physical theory is quite competent to explain the final decrease of leakage, which experiment had demonstrated to occur in the split-ring uniformly magnetised. For Kirchhoff's theorem, already alluded to, in connection with the tangent law for the "refraction" of lines of induction at bounding surfaces, clearly shows that those lines will tend to become more and more exactly peripherical as the applied field is being pushed up, thus diminishing the number of lines leaking away into the air.

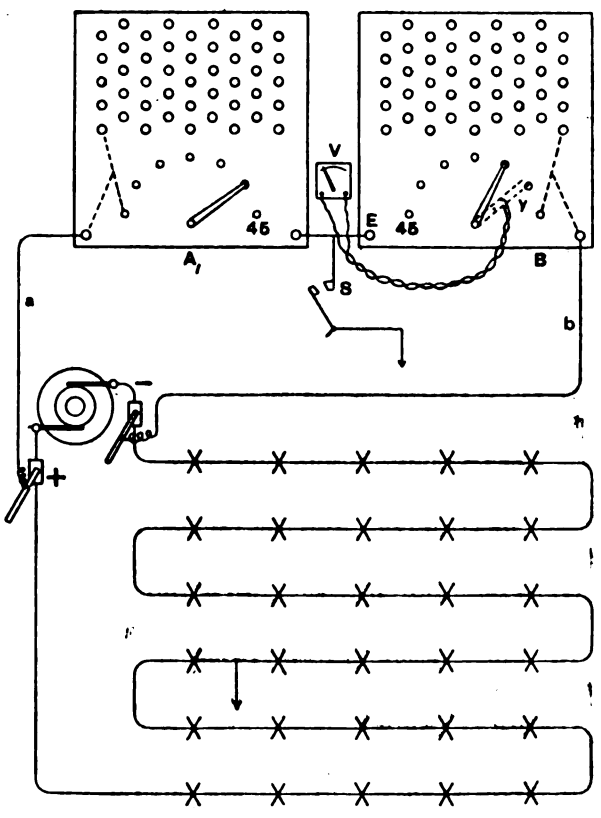
In conclusion, it may be remarked that it is quite possible that leakage may yet increase in particular forms of circuits, where the magnetising field is not uniform all round, *i.e.*, where coils are arranged in some haphazard way, more especially so if there be no coils near the gaps. It has to be borne in mind that on increasing the current in such coils the strong field so applied will finally overpower the self-demagnetising tendencies altogether, and arrange the lines of induction after its own fashion; of course, exactly the reverse happens when weak fields are applied. I intend shortly to investigate this subject a little further by means of a large-sized ring electro-magnet with 12 separate coils, made after my designs by Messrs. Siemens and Halske.

A CENTRAL-STATION METHOD OF LOCATING GROUNDS ON ARC CIRCUITS.*

BY EDGAR E. STARK.

About two years ago the writer made an apparatus utilising the Wheatstone bridge principle, with the object not only to detect a leak on an arc circuit, but to locate it between lamps, irrespective of its resistance. It consists of two banks of 45 120-volt lamps, A and B (*see* figure), connected in series, each bank with a metallic lever sliding over a series of segments connected to the junctions of the lamps in turns. An auxiliary switch y is arranged with two contact blades to touch two adjacent segments of the series, thereby straddling one lamp; the two blades are attached to a Weston voltmeter, V, which can thus read the voltage of each lamp in the series. I use 120-volt lamps on account of the small current they take when run at 50 volts, the current being too small to be noticed when diverted from the arc lamp circuit. These banks or arms, A and B, are connected by a wire, E, which is attached to the switch S with its ground connection. To the other ends of the arms A and B are attached flexible cables, a and b, to connect to the circuit terminals under test.

On installing a set of lamps each arm has to be calibrated. This is done by connecting cables a and b to the + and − ends of a circuit of, say, 80 arc lights; then with all the incandescent lamps in, the levers being on lamp No. 45, the voltage of each lamp is measured by the use of the auxiliary switch y (which is arranged to be unbolted and attached to either board) and the voltmeter. Any lamp that is more than two volts from the average is discarded, and a better one is put in its place. The average voltage is taken, and a lamp selected that equals this average voltage, and this lamp is used hereafter as the standard in computing voltages, &c.



Having the boards thus arranged, after the circuit has been started the cables a and b are attached to the circuit + and − terminals. All the incandescent lamps are cut in; that is, there are 90 lamps in parallel with the outside arc lamp circuit. The ground switch is now opened and closed, and the operator observes if there is any change in the brilliancy of the lamps in the arms A and B. If there is any change when the levers of A and B are in equal and then in largely unequal positions, on the opening and closing, respectively, of the ground switch S, it is indicative of a ground on the arc circuit.

Now comes the "bridge" part of the arrangement. A balance is obtained by altering the number of lamps in arm A or B, as required, so that upon opening and closing switch S there is no change in the voltage of the standard lamp, as indicated by the voltmeter. We have, then, this proportion: The number of lamps on A is to the number of lamps on B as the number of arc lamps on the positive leg of the circuit to the unknown ground is to the number of lamps on the negative leg to the ground. Or A : B :: number of + lamps : number of − lamps. But if we alter A and B so that the voltage of the standard lamp is 50 (or equal to the voltage of the arc lamp on the circuit, if other than 50), then A equals the number of lamps on the positive leg, and B equals the number of lamps on the negative leg to the unknown ground.

The voltmeter will detect a variation of less than ½ volt per lamp. The apparatus will locate between lamps a leak of over 40,000 ohms resistance on an 80-light circuit.

ELECTRICAL STANDARDS.

The meeting of the British Association at Edinburgh was a convenient opportunity for the consideration of electrical standards, but the position of that body in connection with this subject ought to be clearly understood. The value of the work done by the Association is inversely as the prominence or publicity. There are two functions of the British Association which have little to do with Summer Science and the popular element, but which are of very great importance; one of these is the distribution of annual grants of money to assist research, and the other is the work of the special committees. The Royal Society contributes in a similar way to the advancement of science by grants of money, though of course without any competition or interference. But in the work of special committees, the British Association stands practically alone. It would, indeed, be a pity if there were any competition, for this would be inevitably accompanied by interference. The real work of these committees is generally done by one man. The committees rarely meet to any practical purpose until the annual meeting of the Association, when a report is drawn up for presentation to a section. The easiest way of doing this is to append the names of the committee, including all absentees, to the report which is submitted. This gratifies everybody, and, thanks to the disinterestedness of the true scientific spirit, satisfies the man who has done all the work.

It is to such committee work that we owe the creation of the ohm, the volt, and the weber, in 1863, and the original

Digitized by Google

determination of the ohm by MAXWELL and others, from the research carried out at King's College with the assistance of funds granted by the British Association; and nowhere have the initials B.A. been more honourably employed than in the designation of the B.A. unit of resistance. An annual report upon the behaviour of these standards, upon re-determinations and comparisons, and other very important matters, has been a feature of every meeting of the British Association for several years. There has been no attempt or the smallest occasion for an attempt to transfer the responsibility to any other body, and it has been only when proposals have been made to secure the acceptance of the electrical units by other nations that the matter has been discussed by any other body. This was done at a Congress at Paris in 1884, when a number of eminent but self-appointed councillors attempted to create a unit which received the ineffectual and misleading name of the "legal ohm," which served only to create confusion. A similar Congress is threatened at Chicago, but it is to be hoped that before that city becomes filled with Exhibition-mongers and sight-seers, the necessary work will have already been accomplished by men of whom many would probably shun the bustle and excitement and exaggerated delights of a monster bazaar, which seems the last place in the world for important scientific deliberations. The Chicago Congress may adopt the henry, and few will grumble if they approve of megafarads and microboles; they may be induced by M. GUILLEAUME to accept a unit of radiation, and by Mr. PREECE to re-adjust the volt and ampere for the sake of uniformity of indices. The Chicago Congress may be the occasion of the acceptance of the ohm, the volt, and the ampere by the United States Government, if it is thought worth while to delay for a twelvemonth or so what has been already well settled by others.

As we informed our readers some months ago, the time has arrived when scientific men having done all they could in the accurate determination of the chief electrical units, and standards having been constructed by the Board of Trade for their measurement and comparison, the only thing that remained was an Order in Council, by which these standards would receive a legal recognition and value. At this juncture it was very wisely proposed, we believe, by Prof. VON HELMHOLTZ, that some international understanding should be arrived at, and no better opportunity could have presented itself than the meeting of the British Association at Edinburgh. Here it was found by the committee, who really had something to do, that Germany and France were in complete accord with the proposals; and although Prof. ROWLAND, who has been turning his attention of late to that branch of electrical science known as optics, was not present, it was understood that neither opposition nor modification would be pressed from America.

It may be asked, what has the British Association got to do with the Board of Trade and the Privy Council? and the answer is simple. The Board of Trade sought the advice of three bodies, the Royal Society, the Post Office, and the Institution of Electrical Engineers. It was recognised that at the meeting of the British Association a good representation of these three bodies might be expected, and Major CARDEW attended officially, although the committee meeting had no official authority. The adoption of its report, which we publish in another column by the three advising bodies, will be a matter of course; and it may be expected that one of the first duties of the new Government will be the placing of the ohm, the volt and the ampere of QUEEN VICTORIA on the same footing as the yard and the pound, and the other Standards of the Imperial System of Weights and Measures which were made legal and compulsory by the Act of 1824.

GEARING.

BY E. TREMLETT CARTER.

(*Continued from page 428.*)

Rope Gearing.

Where large amounts of power must be transmitted from an engine to one or more machine, it is more economical and efficient to employ ropes rather than leather belting. This form of gearing is used in two ways: the more common practice being to place several separate ropes on V-grooves cut in the rims of cast-iron pulleys, each rope running independently of the others; the alternative method being to wind one continuous length of rope upon all the grooves. In the first of these the risk of breakdown is reduced to a minimum, since the parting of one rope will not cause the others to part, but the ropes are liable to get an irregular distribution of the load and thus to wear unequally. In the second method the parting of the rope arrests the motion of the machinery, which in generating stations may be very serious; but every part of the rope will wear equally, and each span will receive its proper share of the load.

The materials used in rope gearing are tarred or untarred hemp, and cotton. The last of these is the strongest, most flexible and efficient; but it is also the most expensive in prime cost. Hemp is more commonly used, on account of its cheapness. If untarred and dry this material is stronger than if tarred, but is more liable to become fluffy in wear, and has a less frictional grip on the pulley. Untarred ropes will transmit 20 per cent. more power than when tarred, with the same factor of safety. Gearing ropes are usually of three strands without a centre core; the attempts to introduce a core of steel wire having only proved successful in the case of long-distance transmission. The sizes of ropes are usually measured in inches of girth, and vary from 3 to 6½in. The section of material is about 0·9 of the area of the circumscribing circle. Untarred hemp has a breaking tensile strength of about 10,000lbs. per square inch, and an elastic strength (for loads applied for a short time only) of only $\frac{1}{9}$ of this figure. With continuous loads, however, the strands are pulled out on account of the slipping of the fibre, so that a high factor of safety must be taken. To reduce the slacking out which this behaviour of the fibres would cause in rope gearing, a safe working load not exceeding 220lbs. per square inch of section is usually taken. The maximum tension per rope is therefore:—

$$T_2 = \frac{9}{10}\,\frac{\pi d^2}{4} \times 220 = 15{\cdot}76\,.\,g^2,$$

where d is the diameter, and g the girth of the rope in inches.

The coefficient of friction between hemp and cast iron is effectively increased by wedging the rope into a V-groove, provided that the rope does not touch the bottom of the groove. If θ is the angle of the groove (vide *infra*), μ the coefficient of friction between flat surfaces, and μ_0 the coefficient of friction when the rope is wedged into the groove, then—

$$\mu_0 = \mu \text{ co-sec.}\frac{\theta}{2} = 0{\cdot}7 \text{ (in practice).}$$

With this high value of the effective coefficient of friction, and the large angle of embrace which the long-centre distances that are necessary will produce, the ratio of the tight to the slack tension may be very much higher than with belting. Applying the exponential formula given in the section on "Belting," we find that the slipping ratio for an arc of contact of 0·6 of the circumference of the pulley will allow of a practical working ratio of 10. If, therefore, a tight tension of 1,000lbs. exist in the rope, the slack tension need not exceed 100lb., leaving a working difference of tension of 900lb., or 90 per cent. of the tight tension. In belting the working difference of tensions was seen to be only 50 per cent.

Another source of advantage of ropes over belts lies in the much higher velocity at which the former can be run with economy. The greater density of leather causes the detrimental effect of centrifugal force to reduce the most economical velocity of belts to below 3,000ft. per minute; while ropes

Digitized by Google

will run economically up to 5,000. Above 5,000ft. per minute the effect of centrifugal action in increasing the tensions on the rope is so considerable that the rope actually transmits less horse-power than at this speed; while above 3,000ft. per minute it is of sufficient importance to render it advisable to make the proper corrections in estimating the horse-power which a given size rope will transmit. The tension due to this cause is equal to the product of the mass of one foot of rope into the square of its velocity in feet per *second*.

$$C = \text{centrifugal action on rope} = \frac{w.v^2}{32.2}.$$

This force must be deducted from the value of the difference of tensions which would occur if there were no such force; thus—

$$T_2 - T_1 = T_2 - \frac{1}{10}T_2 - C = \frac{9}{10}T_2 - C.$$

And since $$H.P. = \frac{(T_2 - T_1)\,V}{33{,}000},$$

we have, $$T_2 = \frac{110{,}000\ H.P.}{3\,V} + \frac{9\,C}{10};$$

and, $$H.P = \frac{V}{33{,}000}\left(\frac{9\,T_2}{10} - C\right).$$

This gives the horse-power that each rope will transmit, allowing for centrifugal action.

Table *of Values of* C *; or the Centrifugal Tension per Rope.*

V in feet per minute.	girth = 3·14. diam = 1.	3·53 $1\frac{1}{8}$	3·93 $1\frac{1}{4}$	4·32 $1\frac{3}{8}$	4·71 $1\frac{1}{2}$	5·50 $1\frac{3}{4}$	6·50 inches. $2\frac{1}{16}$ inches.
3,000	26	32	39	47	57	76	100
3,600	37	45	56	68	82	109	144
4,200	51	62	77	93	111	148	196
4,800	66	80	100	121	145	193	256
5,400	84	102	126	153	184	245	325
6,000	104	127	156	190	227	304	400
6,600	127	152	190	228	274	367	484
7,200	150	181	225	272	327	436	576

From the foregoing data the following table, giving the horse-power which may safely be transmitted through a single rope, has been calculated. Having selected the size of rope that is to be used, and knowing the amount of horse-power which is to be transmitted by all the ropes, the minimum number of ropes can be calculated by simple proportion. It is usual, however, to add one more rope to allow for parting of any one of the set.

Table *giving the Horse Power per Rope, for Untarred Hemp Ropes.*

V in feet per minute.	girth = 3·14 diam. = 1·	3·53 $1\frac{1}{8}$	3·93 $1\frac{1}{4}$	4·32 $1\frac{3}{8}$	4·71 $1\frac{1}{2}$	5·50 $1\frac{3}{4}$	6·50 $2\frac{1}{16}$
3,000	10·7	13·4	16·6	20·3	24·0	32·5	45·0
3,500	11·2	14·2	17·7	21·6	25·5	34·7	48·1
4,000	11·8	14·9	18·5	22·5	26·6	36·2	50·1
4,500	12·1	15·1	18·6	22·7	26·7	36·4	50·4
5,000	11·8	14·9	18·5	22·5	26·6	36·2	50·1
5,500	10·4	12·9	16·0	19·5	23·0	31·2	43·4
6,000	8·4	10·5	13·0	15·9	18·8	25·4	35·4
6,500	7·0	9·0	11·1	13·5	15·9	21·7	30·1
7,000	1·8	2·3	2·8	3·5	4·1	5·5	7·7

The above table, besides being of use in designing rope gear, brings out very clearly the fact that there is a limit to the advantage of running a rope at high speeds; a limiting speed, beyond which a rope will transmit less horse power in proportion as the speed exceeds the limit. In this table, which is here published for the first time, the limit is fixed at 4,500ft. per minute; but the actual value depends on the working stress, decreasing with the amount of stress allowed per square inch section. With 150lb. per square inch, the most economical speed is about 3,500ft. per minute. For tarred ropes a deduction of about 20 per cent. should be made from the figures given in the table.

The size of rope that it will be best to take in any particular case depends on the velocity chosen and the number of revolutions which the pulley will make. For it is not advisable to allow the diameter of the rope to exceed $\frac{1}{50}$th of the pulley diameter, in order that the rope may not be bent round too sharp a curve on the pulley—a practice which would both injure the rope and waste power. Engine pulleys are very frequently 100 to 120 times the diameter of the rope; machine pulleys are occasionally only 35 to 40 times, but are better if made at least 50 times the rope diameter. Where a high velocity ratio between the machine and engine pulleys is required, this is not always practicable with the larger sizes of rope; it is then better to use a greater number of smaller ropes than to risk the injury which the use of large ropes on a small pulley would involve. Ropes must not be used where it is impracticable to have at least 20ft. horizontal centre distance between the pulleys. Very long distances between the pulleys are absolutely necessary to produce the requisite tensions without straining the ropes up to too small a sag. Their tendency to slacken out very rapidly renders this necessary. Ropes will not, therefore, work well on short centres even with jockey pulleys. Very large pulleys need centre distances of from 25 to 30ft. The pulleys are cast in one or two portions, according to the diameter, and the grooves accurately turned on the faces. Great care is necessary that the grooves shall be of the same depth and at the same angle and width, otherwise the ropes will not all run at the same velocity and will be excessively strained on that account. The

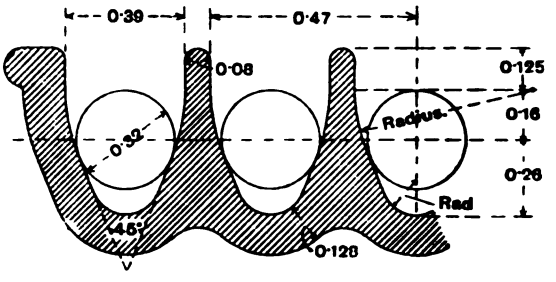

Fig. 4.—Unit = Girth of Rope.

angle of the groove should be from 40deg. to 45deg., and the groove sufficiently narrow at the bottom to prevent the rope touching it at that part. All the ropes should be put on at the same time, care being taken to give them the same amount of sag. If a new rope is put into a set which consists of a lot of old ones, there will be an unequal division of the load, the old ropes getting too large a share and the new one doing hardly any work. Hemp ropes, if designed according to the rules given in this article, will wear well for from five to eight years; and ropes have been known to run for over twelve years without excessive wear. At the end of the time, all the ropes should be renewed; as, leaving on a few that look better than the rest results in trouble and disappointment in running.

The angle of the groove should be sufficiently small to give a good grip on the rope, yet not so steep that the rope is severely crushed between the sides or rubbed on entering or leaving the groove. The proportions of rope grooves are shown in Fig. 4, in which the unit of the dimensions is *g*, the girth of the rope.

In designing rope gearing, it is often necessary to ascertain the space which the ropes will occupy when under any given tension, and this is best obtained by means of a graphic method. In the first place it will be necessary to find the amount of span which the ropes will require in order that a given tension may be produced with a given amount of sag; or, conversely, to find the sag which a given span and tension will produce. The free parts of a suspended rope hang in a curve which approximates to a parabola, and is called a *catenary*. The analysis of this curve is complicated, the general equation being—

$$y = \frac{p}{2}\left(\epsilon^{\frac{x}{p}} + \epsilon^{\frac{x}{p}} - 2\right) = \sqrt{S^2 + p^2} - p,$$

where p is the parameter and s is the length of the curve. The *parameter* is the ratio of the horizontal tension at the

Digitized by Google

lowest point of the curve to the weight of unit length of the rope. The writer has devised a graphic method for each of the cases required in practice, which is sufficiently correct for general work if constructed on a large scale. Owing to the fact that the parameter of a hemp rope catenary is so much larger than the span of the curve, it is well not to adopt a scale of less than ½in. to a foot. The method devised by the writer for determining the span when the sag. and tension are known, is shown in Fig. 5. Let B be the point of contact of the rope

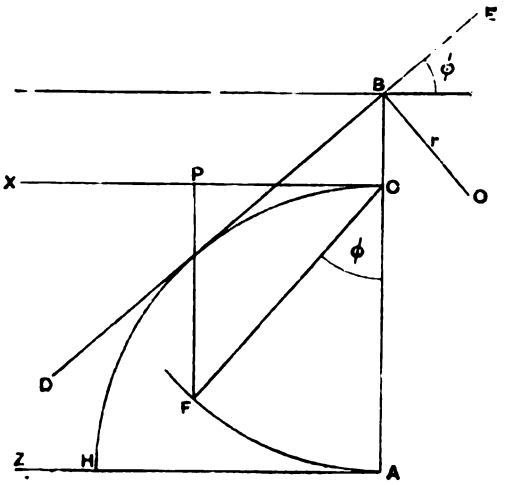

Fig. 5.

with the pulley. From B draw the vertical B A equal to the ratio of the tension to the weight of a foot length of the rope. Mark off B C on B A, equal to the required sag. Then A C is the parameter of the catenary. Draw horizontals C X and A Z. From centre A, with radius A C, draw the arc C H; and from B draw B D at a tangent to this arc. Produce D B to E, then B E is the tangent to the pulley at the point B, and indicates the inclination of the rope at that point. Call ϕ the inclination of the rope to the horizontal at B. Draw B O at right angles to B E and equal to the radius of the pulley. Then O is the centre of the pulley. To find the lowest point on the rope curve, from centre C with radius C A describe the arc A F, making the angle A C F equal to ϕ. From F draw F P normal to C X. Then P is the lowest point on the curve. If the two supports are at the same level, the distance P C is equal to half

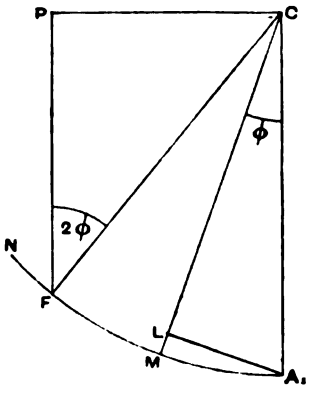

Fig. 6.

the free span; but, if they are at different levels, the operation must be repeated for the other side, or the left hand half plotted from the already determined right hand half by continuing it backwards. (*See* Fig. 7).

In the converse case, in which it is required to find the sag., the tension and span being known, the graphic method is shown in Fig. 6. Draw the horizontal line P C equal to the entire free span; and from C draw C A at right angles to P C, equal to the ratio of the tension to the weight of one foot of the rope. From centre C, draw the arc A N; and from P draw P F at right angles to P C, cutting this arc in F. Bisect the arc A F in the point M; and join M C. Then the angle A C M is equal to ϕ. From A draw A L normal to the line C M; then C L is equal to the parameter of the catenary, and L M is equal to the required sag.

It is sometimes necessary to plot the entire curve for each rope, in order to see what space it will occupy and how the two curves will lie in relation to one another. To determine this the tension in each half of the rope should be taken both for when the rope is at rest and for when it is driving. The sag on the top half is greatest when in motion, but on the bottom half it is greatest when at rest. In Fig. 7, the manner of setting out the semi-curve is shown, the *parabola* being taken, as being sufficiently near to the catenary for practical purposes. P is the lowest point on the curve, and B is the point of contact with the pulley. B C is drawn equal to the sag; and P C, equal to the horizontal distance between P and B, is drawn at right angles to B C. The lines P C and B C are divided into an equal number of equal parts at points 1, 2, 3, 4, on P C, and 1′, 2′, 3′, 4′, on B C. Point P is joined to each of the

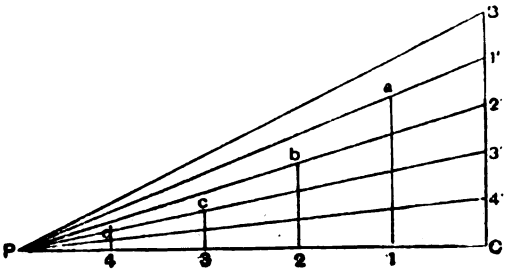

Fig. 7.

latter set of points, as well as to B; and verticals are drawn from the former set of points, cutting the diagonal lines in points *a*, *b*, *c*, *d*, &c., which, together with B and P, are on the required curve. The other half of the curve may be drawn in a similar manner, the method being exactly the same whether the supports are or are not at the same level.

(To be continued.)

THE CONSTANCY OF ELECTRICITY METER CONSTANTS.

Two Ferranti continuous-current meters (Nos. 122 and 127), made in 1885, were fixed in a private residence, and have been in practical use there for seven years. They were both on the same principle as the present form, but were of the earliest type, with cast-iron magnets, the polar face being enamelled, and the ring completing the mercury chamber being plated with nickel.

No. 122 was at work for five years with 20 amperes maximum current, and for two years with 25 amperes, nothing having been done to the interior in the meantime. The constant (*i.e.*, the number of revolutions per Board of Trade unit supplied at 100 volts) was determined by the Kensington Court Company when the meter was first installed to be 60. The following determinations by the same Company were made during the week ending June 25, 1892, the starting current being 0·9 ampere:—

Time.	Current.	Constant.
2 hours	20·5	54·4
2 „	10·21	58·7
3 „	6·58	50·4
		163·5 ÷ 3 = 54·5.

The constant had thus become 9 per cent. low in seven years. The Company, however, state that the measuring instruments used in 1885 show a difference with the present ones, which brings the present constant to within 5 per cent. of its original value.

The Ferranti Company then took the meter, and, without cleaning it, changed the mercury. It was then found to start somewhat earlier, but the constant was not very appreciably affected. The meter was then opened, and it was seen that the recording wheels required cleaning, but were not affected by the mercury. The spindle was not worn either at the top or

Digitized by Google

bottom pivot. The pinion was also unworn. The fans were still in a true position on the spindle, and the blades had not been affected by the mercury. The mercury had not escaped or evaporated from the meter, and there was still twice the amount sufficient. It had a slight scum on the top. The jewel at the bottom was dirty, and this retarded the rotation of the meter at low readings. The enamelled faces of the poles and the nickel-plated ring, which together form the mercury chamber, were coated with an amalgam. The number of revolutions made by the meter as it stands at present is 17,820,680.

Meter No. 127, in use for seven years, was cleaned in 1890, the original constant as determined by the Kensington Court Company was 48. As again determined during the week ended June 25, 1892, it was as follows :—

Time.	Current.	Constant.
2 hours	21·29	51·7
2 „	10·21	49·0
3 „	6·56	43·0

The starting current was 1·45 ampere. The remarks made as to the condition of meter No. 122 on examination apply also to this one.

ELECTRICAL DISCHARGES.
